THE ELECTRICIAN

AND

ELECTRICAL ENGINEER.

A Monthly Review of Theoretical and Applied Science.

VOLUME VI.—1887.

(January to December.)

NEW YORK:
ELECTRICAL PUBLISHING COMPANY,
115 Nassau Street.

American Institute of Electrical Engineers, The 209, 210
American Institute of Electrical Engineers—May Meeting..... 169
Death of Three Prominent Men—Prof. E. L. Youmans, Mr. John Roach, Gen. Wm. B. Hazen.... 42
District Messenger Service, Degeneration in..... 2
Edison Incandescent Lamp Case in England, The..... 82
Electricity for Street Railways...209
Electricity on Street Railways...425
Electric Lighting, The Fire Risk in 41
Electric Lighting, The Progress of 329
Electric Light Figures, Some Prophetic..... 330
Electrical Distribution by Induction..... 290
Electrical Transportation, The Future of..... 289
Electrical Exhibition of the American Institute, The..... 330
Efficiency of the Direct *vs.* The Alternating System of Distribution 426
Farrago—A French Joke. 43
Faure and Brush Patents, The —Storage Batteries..... 1
Fire Risk in Electric Lighting, The 41
Future of Electrical Transportation, The..... 289
Hazen, Gen. William B., Death of 42
Jubilee Days 249
Let This be a Warning..... 210
Long-Distance Telephony..... 3
National Electric Light Association, The..... 81, 330
Notes..... 3, 43, 82, 130, 170, 210, 250, 290, 291, 330, 386, 426, 466
Patent Office Methods..... 129
Patent Office Reform..... 465
Progress of Electric Lighting, The..... 329
Pan-Electric Non-Suited..... 385
Roach, John, Death of..... 42
Street Railways, Electricity for..209
Street Railways, Electricity on...425
Some of the Results of Telegraphic Competition..... 425
Semi-Centennial of Industrial Electricity, The..... 329
Some Prophetic Electric Light Figures..... 330
Subways in New York..... 385
Storage Batteries—The Faure and Brush Patents..... 1
Street Railway Traction in New York..... 466
Telegraphic Competition, Some of the Results of..... 425
Telephone Profits 169
Telephony, Long-Distance..... 3
Youmans, Prof. E. L., Death of.. 42

[*Entered at the Post Office at New York, N. Y., as second class mail matter.*]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

NEW YORK, JANUARY, 1887.

ANNOUNCEMENT TO SUBSCRIBERS.

WE are pleased to recognize the fact that a principal source of the growth of our subscription list is the favorable commendation of the ELECTRICIAN AND ELECTRICAL ENGINEER by those who are already subscribers, to their friends and acquaintances

We shall continue our endeavors to deserve your appreciation and good-will, by keeping up, and if possible improving the quality of our paper. To any of our present readers who may find it in their way to increase our list, we offer rates for 1887 as follows:

For your own subscription	and	1	new name	.....	$5	00
"	"	"	"	2	"	.....	7	00
"	"	"	"	3	"	.....	9	00
"	"	"	"	4	"	.....	10	00

This offer will hold good until April 1st.

The *Telegraphic Journal and Electrical Review*, London, will be supplied for one year in conjunction with the ELECTRICIAN AND ELECTRICAL ENGINEER for the additional sum of $4.00 with any subscription.

In addition to the usual methods prescribed for making remittances, money orders issued by the American, United States or Wells Fargo express companies will be found safe, cheap, and convenient.

Very respectfully yours,
ELECTRICAL PUBLISHING CO.,
115 Nassau St., New York.

STORAGE BATTERIES.—THE FAURE AND BRUSH PATENTS.

THE use of storage batteries, or accumulators, has met with a somewhat tardier development in this country than in Europe. Since the discovery was announced a few years ago of the mechanical method of preparing the electrodes for receiving a charge, thus supplanting the tedious electrical process of forming, requisite in Planté's secondary battery, there have not been wanting many believers in the ultimate commercial success of electrical accumulators as a very important addition to the resources of electrical engineering. While inventors directed their efforts to devise further improvements, schemes of considerable magnitude were set afoot through the organization of stock companies to acquire patent rights and develop the expected business by the manufacture and sale or renting of accumulators. The early attempts in this direction were not very successful as practical business undertakings, however greatly they may have redounded to the profit of speculators in patents. Legal complications arose, through claims of rival interests to the control of patents; and such an entanglement ensued as to suggest that some of the methods of the illustrious Philipart had been acquired by the enterprising gentlemen engaged in exploiting patents for foreign inventions in storage batteries. The methods of construction of the batteries had not yet been sufficiently developed to produce a trustworthy commercial accumulator.

Meantime, Mr. Charles F. Brush was busy following up his early invention in storage batteries, and supplementing it by efforts directed to the improvement of details of construction. Mr. Brush has been one of the persistent believers in the future efficiency and importance of electrical storage. His storage battery is now, and has been for a long time, in constant service by the Pennsylvania Railroad Co., in its drawing room cars.

The Brush Electric Co., of Cleveland, Ohio, own the Brush patents for storage batteries. They are building and perfecting a battery which, like the Faure battery, has mechanically formed plates.

Through the organization of the Electrical Accumulator Co., which, in a recent circular, announces its readiness to supply accumulators for a variety of uses, "combining the invention of Faure and improvements thereon," the greater part, if not all, of the conflicting interests and ownerships in the Faure and other patents, alluded to above, are understood to have been consolidated and brought under the control of that company. As our readers are doubtless aware, the company has been organized and is managed by men of wide experience in electrical business and of recognized ability in corporation management. Their confidence in the future of the business which they have undertaken is attested by the establishment of their factory at Newark, where they are now

Digitized by Google

producing accumulators; and by the guaranty of efficiency which is offered with accumulators sold by them.

The fundamental feature in the making of the storage battery for practical use and commercial business is clearly the substitution of the mechanical preparation of the plates for the slow process of electrical formation as practiced in the Planté battery. For the control of the invention of mechanically formed electrodes there is likely to be a contest.

The Faure patent of January 3d, 1882, No. 252,002, and the Brush patents of March 2d, 1886, Nos. 337,298 and 337,299, appear to cover substantially the same invention, to wit, the mechanical formation of electrodes ready to receive a charge, in contradistinction to the electrically formed electrodes previously well known. Faure's invention was patented in France, October 20th, 1880. His application for a United States patent was filed April 20th, 1881. Brush's applications were filed June 12th and 13th, 1881, respectively. Whether by oversight on the part of the patent office or otherwise, the Faure patent of January 3d, 1882, was issued, notwithstanding the pendency of Brush's applications.

As soon as the Faure patent issued and the claim became public, Brush took the only course that was open to him. He demanded an interference between his applications (of which there were several) and the Faure patent, and publicly announced in the New York press on May 17th, 1882, his rights and claims in the matter, and that they would be enforced. The interference was declared May 13th, 1882. Two other parallel interferences were also declared and another application by Faure was included, and other parties and claimants to the broad invention were brought in. Eventually the three interferences were entitled respectively, Keith *vs.* Shaw *vs.* Maloney & Burger *vs.* Brush *vs.* Faure; Keith *vs.* Shaw *vs.* Brush *vs.* Faure; and Maloney & Burger *vs.* Brush *vs.* Faure. And they proceeded together, the issues or claims involved varying slightly in the three interferences, but including the broad generic claim to the mechanical process and battery as distinguished from Planté's.

These proceedings in the patent office were greatly prolonged through motions to postpone the interferences, which were appealed through every tribunal to the secretary of the interior. Pending these delays in the patent office, and about four years ago, the Faure people began a suit for infringement of the Faure patent against the Brush company. An answer was promptly filed by the Brush company, but the Faure people, apparently, have never since taken any further steps forward with the suit. In the patent office proceedings, the testimony of all parties was finally completed and the interferences argued, and decided, all three of them, in favor of Brush, and on the resulting appeals those decisions were all sustained, and patents were in consequence issued to Brush on March 2d, 1886. The decision of the interferences in favor of Brush, and the issue of his patents, exhaust the powers of the patent office in determining title to the invention, inasmuch as the patent office cannot annul a patent once issued. As evidence they create a presumption in favor of Brush, but the control of the invention must be finally adjudicated in the courts.

The Brush Electric Co. announce their purpose to retain in their own hands the business of manufacturing, selling and using mechanically formed storage batteries or plates, and to enforce their rights under the Brush patents in the courts, against any and all who may build, sell, or use such batteries.

There seems to be no good reason to doubt that storage batteries, sufficiently improved—in the troublesome details of construction that have so long retarded their success—as to be conveniently manageable, will soon be freely offered for general electrical purposes.

DEGENERATION IN DISTRICT MESSENGER SERVICE.

Time was when the average District Telegraph messenger bore some likeness, in both appearance and gait, to the bright, tidy and swift-footed youth depicted still on the sign-boards of the District Telegraph companies. In those good days the neatly dressed messenger boy came promptly when called, entered room or office quietly and politely, and, best of all, went about his errand in a manner indicating some drilling in carefulness and despatch. The service was good in all points. One could depend on having any sort of errand well and speedily done.

Now-a-days the service is undeniably poor; the old type of messenger seems to be well-nigh extinct; instead of him, with his good manners and efficiency, the messenger of to-day is a more or less unkempt youth, who lounges or plunges into one's room, announcing his arrival, at the threshold, with a vociferous cry of "*Call*," often after tiresome waiting and repeated calls on the part of a subscriber. His slovenly appearance and boisterous demeanor, however disagreeable, are less serious annoyances than his frequent tardiness and incompetency. He could be forgiven much if he would only come quickly when called, and "get there" promptly when despatched on an errand. He sometimes seems to be totally ignorant of the topography of the city, and requires, in addition to street and number written on parcels entrusted to him, minute verbal directions as to localities and streets. Car fare is a perennial subject of interest to him; a suggestion from him on that point is forthcoming on the slightest provocation.

The peculiarities of his progress through the streets are suggestively amusing to an observer who is not at the time awaiting service at his hands. Peanuts and apples engross a fair share of his attention; a serene and deliberate survey of the architecture of the vicinity sometimes absorbs all his powers; an accident or disturbance anywhere within reach of his eyes or ears draws him into the front rank of the surrounding crowd; in fact, he seems to realize and improve to the full his excellent opportunities of observing and enjoying the street sights of the city. When these fail him his fertile mind is often equal to the task of providing some diversion from the tedium of a long and uneventful walk.

But let us not be too hard on the boys. They are neither better nor worse than other boys of similar age and occupation. Boys and men are rare who render better service than they are trained for and required to perform. There is every indication that the present generally observed inefficiency of the messenger service of the District

Digitized by Google

Telegraph companies is due to a lack of necessary training and discipline of the boys, on the part of the managers. The service when well regulated is an invaluable convenience to the public. It is a pleasant reminiscence to recall the promptness and courtesy of the earlier messenger boys. We believe that systematic instruction and drilling of the force was part of the management in times past. If still kept up, it must be in a very formal and perfunctory manner, lacking any element of painstaking or thoroughness.

We trust that the service need not still further deteriorate before an effort shall be made to restore it to its former efficiency.

LONG-DISTANCE TELEPHONY.

The American Telephone and Telegraph Company have made such substantial progress in their work as to have now twenty-four wires between New York and Philadelphia ready for service. It is some weeks since the lines were put to use, although they have not yet been formally opened to the public. The practical success of telephonic conversation over these lines seems quite perfect. By the use of metallic circuits induction disturbance is eliminated. The service is quite as good as on ordinary city lines; better than on many of the latter, on which fizzing, buzzing and rapping, occasionally disturb the serenity and ruffle the temper of any but the most angelic subscribers. The long-distance telephone service can hardly fail of hearty appreciation and extensive use on the part of business men. Its use for five minutes will often serve all the purposes of a personal interview, and should save many inconvenient and expensive journeys between cities connected by telephone. It has a large legitimate field without trenching upon the sphere of the telegraph; although it seems to us that when generally established, and when the public shall have become well acquainted with its facilities, it will in some measure reduce the amount of telegraphing. Possibly the result may be analogous to that of the competition between gas and electricity in the business of lighting. Men interested in gas lighting say that the introduction of electric lighting has in many localities effected an increase in the consumption of gas; that it has created a demand for more light. Be that as it may, we cannot have too many, nor too good, nor too far-reaching means of quick communication.

In the informal use of the lines between New York and Philadelphia during the past few weeks, a somewhat amusing difficulty was developed, having its origin in the average American's quick scent for "chaff." We happened to be in the office of the company in Philadelphia some two weeks ago, and were impressed by the rapidly rising wrath of a gentleman endeavoring to communicate with a New York correspondent, and obviously meeting with exasperating and insurmountable obstruction. After repeated vain attempts the gentleman gave it up. He had been duly connected with the proper party in New York, the telephones worked perfectly, but he had utterly failed to convince the New York party that his telephone was connected with Philadelphia, receiving nothing but derisive replies to his repeated asseverations that he was veritably himself, and talking from that city. We were informed by the manager that this was but one of several similar occurrences.

It was a happy thought of the Council of the American Institute of Electrical Engineers to attempt monthly meetings of the Institute, at which a dinner precedes the paper and discussion of the evening. The presence of some 30 members, December 7th, and their hearty enjoyment of the social feature of the evening, as well as their general interest and participation in the discussion of Mr. Martin's excellent paper on Electric Street Railways, were conclusive evidence of the acceptability of the plan of monthly evening meetings. We print Mr. Martin's paper, and the subsequent discussion, in full, in the present number.

The air is again thick with rumors of consolidation arrangements between the Western Union and Baltimore and Ohio Telegraph companies, although the usual denials of anything of the sort from prominent officials of both companies are not published. Rumors come and rumors go, but the sending of telegrams goes on forever; and we have little doubt that the business community would be pleased to continue telegraphing between important centres of trade at present low rates rather than to see the principal competitors for their business strike hands and put up charges.

The total number of messages sent by the Western Union Telegraph Co., year ending June 30th, 1886, is given as 43,289,807. Assuming that 15,000,000 to 20,000,000 messages were sent by all other companies in the country, the somewhat interesting result appears that the whole number of telegrams for the year was about one per head of population.

Continuing our graphic analysis of the business of the Western Union Telegraph Co. for twenty years, from the figures of the president's report of 1886, we print in another column a chart showing average tolls and average cost per message for each year since 1866.

Professor Anthony favors us with a copy of the "Examination in Electrical Measurements, Course of Electrical Engineering, Cornell University, Fall Term, 1886," which we print in another column. The questions indicate the high order of instruction furnished at Cornell. It seems particularly fitting that this University, whose founder was so closely related to the establishment and development of the electric telegraph, should assume a leading position in electrical instruction.

The interest taken by gas companies throughout the country in electric lighting is very noticeable. Our news columns, as well as those of other electrical and trade journals contain a constantly increasing number of notices of gas light companies adding electric lighting to their business or seeking charter privilege to do so.

Our valued, but modest, contributor, Mr. Carl Hering, writes us to say "You made an error in stating in your journal that I was the electrician of the Philadelphia Exhibition of 1884. In justice to Professor Thurston, I must call your attention to the fact that I had the title of assistant electrician and nothing more." This refers to our list of contributors in our prospectus for 1887, in which we named Mr. Hering as "Electrician of the Electrical Exhibition at Philadelphia, 1884." Our readers who are well acquainted with the position of Prof. Thurston in the Electrical Exhibition, will doubtless have made the correction for themselves.

ARTICLES.

INCANDESCENT LIGHT LEADS.

BY CARL HERING.

As incandescent lamps are connected in multiple arc, and as they require to have a constant potential at their poles, there must in all cases be a higher potential at the machine, and a loss of potential in the leads. As this loss of potential depends on the resistance of the leads and the current in them, it remains constant only for the same resistance and current, and, therefore, when the lamps are cut out the current will change and consequently also the potential, or in other words the lamps will have their potential increased when their number is reduced, and *vice versa*.

The only ideally perfect method of running incandescent lamps therefore, is to have a pair of independent leads from each separate lamp to the dynamo, and to have them all of the same resistance, in which case the cross-section will be increased directly as the distance, that is for double the distance the leads will have double the cross-section, or four times the weight. This will evidently be a perfectly self-regulating system, but it would in most cases be too expensive, as for 100 lamps there would be 200 leads. There is however one important point about such a system which is greatly in its favor. There are two expenses to be considered, one the cost of the power lost in the leads and the other the interest on the copper conductors; both of these are running expenses. If we start with very heavy leads and calculate these two expenses for successive diminutions in the size of the leads, we will obtain the results about as shown by the two curves in figure 1. The

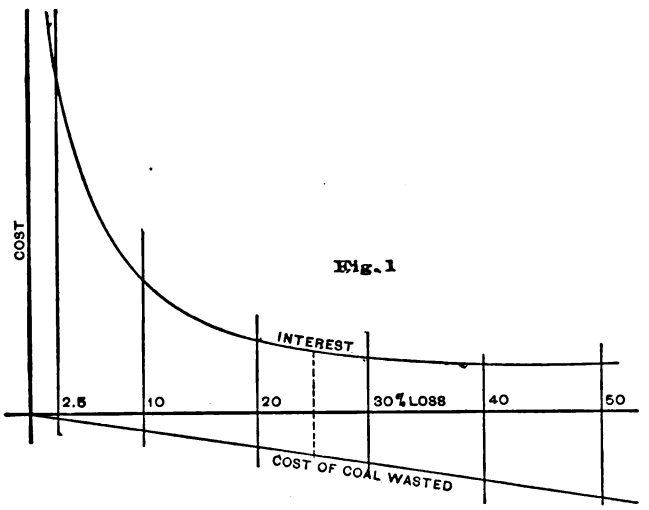

Fig. 1

upper curve is the interest on the copper for different losses in the leads and the lower, which is a straight line, the cost of the lost power. The sum of the two, that is the distance between them, represents the total expense, which in this particular case was least when the loss of potential in the leads was about 22 per cent. This result may at first seem surprising, but it will be seen that the power expense is very small as compared to that of the copper. If the lamps are burned only a small portion of the day, the loss of potential may even be taken still greater as the interest is for the full time and the duration of the power loss is less. In the ordinary system such a great loss in the leads cannot be allowed, as it would not be self-regulating when lamps are cut out.

In cases where all the lamps are always in circuit, such a heavy loss may safely be allowed even in the ordinary system, thus effecting a great saving in expense, both first cost and running; it is necessary in that case to replace a lamp as soon as it goes out, otherwise the others will soon all follow in turn. In cases where whole groups of lamps are cut out at one time, a separate pair of mains may be laid to each group from the dynamo, and the system will then be self-regulating, while the loss in the leads may be taken as quite great, say 15 to 20 per cent., thus saving considerable copper.

In the ingenious system of Gordon's divided main, from a description of which figure 4 was taken, this principle of small mains is made use of by dividing the main from the dynamo to a point in the midst of the lamps into a number of smaller insulated mains, which are in turn cut out at the dynamo end as the lamps are cut out, thus accomplishing practically the same results as those of the method first described. Perfect regulation, and great saving of expense may thus be accomplished.

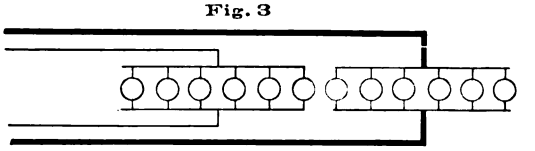
The next best way to insure approximate regulation of constant potential at the lamps, is to make the conductor so thick that the fall of potential will be so small that its variation will be insignificant. This is the ordinary method in which the loss of potential allowed may be 2, 3, and even 4 or 5 per cent., the latter only in cases where the leads are well distributed with reference to the lamps. In such a system a pair of mains should be laid from the dynamo to near the centre of the group of lamps to be supplied by these mains, and from this point only, should the branch or distributing wires be laid to the lamps. These distributing wires should all be calculated for the same loss of potential, and should therefore be thicker the farther the lamp. In a good system it is preferable, when distances are great, to run separate distributing wires to each group, as in figure 3, in preference to running one secondary pair of mains from which lamps are supplied at various distances, as in figure 2. When lamps are situated near the

Fig. 2

course of the principal mains, it is preferable, when distances are great, and when a comparatively great fall of potential is allowed, to run a pair of distributing leads from the ends of the mains back to the lamps, rather than to connect the lamps directly to the mains, or else to use comparatively high resistance distributing wires direct from the nearest point on the mains.

In this system the mains are generally very large, and in order to facilitate laying and handling, it is generally found preferable to use a number of thick wires in parallel. These separate wires usually have their ends permanently connected with each other at the distribution centre. But as will be seen by comparing this system with the one first mentioned, a much better distribution may be had with these same parallel wires by connecting each one to a separate independent group of lamps, instead of connecting them all with one another at the distribution centre. The increase of potential due to cutting out lamps is then much

Fig. 3



smaller than if the parallel wires act as one main; it approaches more nearly to the so-called perfect system.

The practice of having lamps requiring slightly different potentials, for different distance along the mains, is not good, except where the groups are entirely distinct and separate, as in different buildings for instance, and even then it is preferable if not essential, to have separate independent mains from the dynamo to each group.

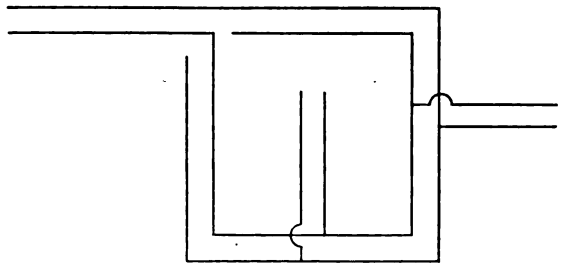
In cases where there are many lamps between two parallel mains, as in figure 2, it is bad practice to diminish

Digitized by Google

the size of the leads toward the end, when the distances are great; it should on the contrary be increased, or at least be equally large, in order to approximate to constant potential. When in this case the number of lamps is large, it is preferable to run several pairs of mains to successive groups, making the longer mains thicker, as shown in figure 3.

A very good system, which however is limited in its application owing to the position of the lamps, is to run the mains as shown in figure 4. The fall of potential, or resistance of the leads, will evidently be constant for each

Fig. 4



lamp as long as they are all burning, but for variations in the numbers of lamps it is only approximately self-regulating like the others. When all lamps are always in circuit, this system permits of great saving of copper, at the same time giving equal potentials, when the loss of potential allowed is quite great, say 15 to 20 per cent.

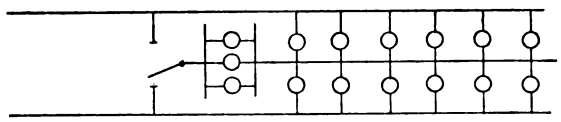
In cases where a single pair of mains is laid from the dynamo to a distributing centre at some distance from the machine, a considerable saving of copper may be effected and at the same time some power saved, if the potential is maintained constant at the distributing centre, but increased at the dynamo proportionately to the number of lamps burning. In this case the mains may be made small, and the loss in them comparatively great; the percentage of power lost in the mains then evidently decreases with the number of lamps. This system is even better than the first one described and termed the ideally perfect system, provided the leads are well distributed from the ends of the mains, as it saves more power and requires only one pair of mains for the greater part of the distance, instead of a large number of separately insulated small wires. It is however limited in its application to special cases, in which a group of lamps is at a comparatively great distance from the machine, and only one such group can be supplied by a machine. Furthermore, the machine has to be regulated to increase its potential in a certain proportion with the current. This can readily be done in compound machines, if the series windings be increased sufficiently to make this difference. If the machine is regulated by hand or by an automatic regulator, a pair of small return leads may be laid from the distributing centre back to the regulator, the potential of these wires, that is, that at the distributing centre, must then be maintained constant, and that at the machine, therefore, increased.

To illustrate this method of distribution by an example, let us suppose 150 lamps of 100 volts and .6 amperes, to be run in a group at 2,000 feet from the machine. Assume first a loss of potential of 25 per cent. in the mains; the greatest potential at the dynamo will therefore have to be $\frac{100}{75} = 133.$ volts; that is, there will be 33 volts lost in the mains. As the greatest current is $150 \times .6 = 90$ amperes, the resistance of the mains must be $\frac{33}{90} = .37$ ohms, and as the length is 4,000 feet, it will require about a No. 0, B. and S. wire. When only one lamp is burning the fall of potential will be $.6 \times .37 = .22$ volts, making the potential at the machine practically 100 volts, and the variation from 100 to 133 volts. The mains will not heat too much as this wire will carry 90 amperes without danger. To compare this with the ordinary method, allow say 4 volts or 4 per cent. loss in the mains; the resistance will have to be $\frac{4}{90} = .0444$ ohms for 4,000 feet, or in other words, it will have to be 9 times as great in cross-section, that is, 18 wires, size 0, or an increase of 16 lengths of 2,000 feet each, above what was required in the first case. The interest per day on this additional amount of wire and on the cost of laying it, will be found to be slightly greater than the extra cost of the excess of power lost in the first case over that lost in the second, that is the difference between 25 per cent. and 4 per cent. Better regulation will be effected for the smaller mains than for the larger ones, provided the machine regulates well; for in the latter case the potential will vary 4 volts at the distributing centre, while it will be constant in the former. The best proportions will vary for different circumstances, and should therefore be determined for each case. The smaller mains will be more economical for greater distances, and *vice versa*.

The three-wire system is well known to all. It is limited in its application to cases in which the two groups of lamps are always nearly equal; if for instance, all the lamps of one group, that is between two of the three mains, be turned off, the fall of potential will be very great, and the regulation very bad.

Another system which is quite similar to this one, but has the advantage that only one machine of double the potential is required, instead of two as in the Edison three-wire system, is used by the Keystone company in their central station plant in Philadelphia. It is shown in figure 5. A compensating group of lamps is kept at the station,

Fig. 5



and is so connected that it can be switched into either side of the equalizing lead; thus restoring the balance. This is not automatic, and therefore requires constant attendance.

Numerous rules, formulæ and tables have been published, for determining the size of leads for incandescent lighting, most of which, however, are more or less complicated, and will therefore find limited use in practice, the natural result of which is that instead of properly determining the leads the engineer will use his "judgment" in selecting the sizes, which is little short of guessing. In cases where tables are used considerable calculation is necessary to make the tables, and a new set has to be made for a lamp of a different current or potential.

In order to meet the demands of good engineering practice, which are: reliability of the method, labor saving in the calculations, accuracy of results, flexibility and simplicity of the method, and freedom from errors of complicated calculations—the writer has devised the following method which is found by extended experience to answer all these requirements.

As described before, the leads must be calculated for a certain allowable loss of potential in them. This is ordinarily from two to five per cent., the greater of which should be allowed only when the number of lamps cut out at any time is not a very large proportion.

Let V be the number of volts lost in the leads,
R the resistance of the leads,
C the current in them,
A the cross-sectional area of the lead in square mils,
L the length in feet of the whole lead.

Then
$$C = \frac{V}{R} \text{ and } R = \frac{L}{A}\ 8.22$$

from which the general formula is deduced, namely:

$$A = \frac{C\,L}{V}\ 8.22,$$

Digitized by Google

or if D is the distance from dynamo to lamps, in which case $L = 2\,D$, then

$$A = \frac{C\,D}{V}\ 16.44.$$

This formula is quite general and is applicable to all lamps or losses of potential. The constant 16.44 is not an arbitrary one, as is sometimes supposed, but depends only on the resistance of the copper, as shown above.

In practice this formula would be used in a simpler form, as we may substitute for C the number of lamps n multiplied by the constant current c for one lamp, and as the loss of potential is a constant for a certain installation, it may be combined with the constant, 16.44, thus giving the simple form

$$A = n\,d\left(\frac{16.44\,c}{V}\right)$$

in which the latter quantity is calculated once for all. Thus the cross-section is the number of lamps multiplied by the distance in feet and by a constant. For 4.11 volts loss of potential, and .75 amperes per lamp, this reduces to

$$A = 3\,n\,d;$$

that is, the lamp-distance, or lamp-feet multiplied by three is the cross-section. By means of a table of cross-sections of the different sizes of wire, such as every electrician has, or such as was published in the ELECTRICIAN AND ELECTRICAL ENGINEER, pp. 182 or 268, vol. v, the diameters or gauge numbers may be found directly without calculation, from the cross-sections. It is especially convenient when several wires are to be used in parallel.

The formula might be made to give the diameter directly, but this is not to be recommended as it involves a square root calculation which is objectionable except for single cases.

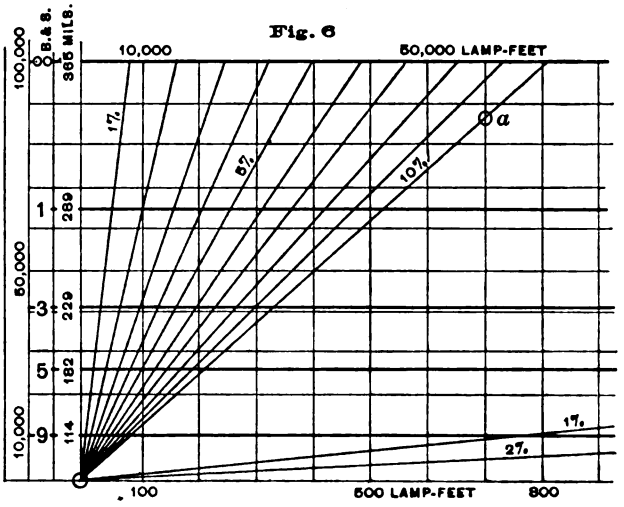
In cases in which a great fall of potential is allowed, in which the wires will heat slightly, the resistance constant 8.22 must be taken slightly higher. In most of such cases it will suffice to take the cross-section slightly greater than that given by the formula, instead of changing the constant.

In general, the mains lead to a distributing centre, and should, therefore, be calculated separately for a certain part of the loss of potential, while the distributing leads should be calculated for the rest of the loss. If a portion of the lamps are at a considerable distance from this distributing centre, they should have a separate independent sub-main from the distribution point, which will then allow the same fall of potential for these lamps as for all the others. There is no reason other than economy of copper why the distant lamps of a group should not have the same potential as the rest, and be maintained as nearly constant as the rest.

For calculating the size of leads the ordinary mechanic's slide rule may be very highly recommended, as by means of it the computations may be made in almost the same time as it would otherwise take to write down the figures, while the chances of making a mistake are not nearly as great as in the ordinary calculation, unless it is checked. Even the diameter can then be readily found with but a very slight additional adjustment of the slide, thus avoiding entirely the use of any tables.

When many computations have to be made, as for instance in a somewhat complicated system of distribution, the following graphical method will be found not only to save considerable time, but also to reduce to a great extent the probability of an error in the calculation. On a piece of accurately prepared cross-section paper (the decimal lithographed preferred to the ruled), mark the figures and lines as shown in part in figure 6. A convenient size is about 18 inches high and two feet long. In the first vertical column mark off, to a convenient scale, the cross-sections embracing the range of wires used for leads. In the next column mark off the sizes of the wire in numbers of the gauge used, corresponding to their proper areas of cross-section in the first column, as obtained from a table. In a third column may, if desired, be laid off similarly the diameters of the sizes of wire obtainable, in the proper places with reference to the first column. These three columns will then correspond to a table of cross-sections, diameters, and gauge numbers. Through the points of the second column, and any in the third corresponding to sizes used, draw bold horizontal lines. On the upper side of the paper mark off in ten-thousandths, numbers ranging from 1 to about 200,000.

Fig. 6



For the particular lamp for which the scales are to be made, calculate, from the formula, the required cross-section for any fixed number of lamps at any fixed distance, for a loss of potential of 10 per cent. Mark off this point, a, in its proper position, considering the figures in the horizontal scale to represent lamp-feet, that is number of lamps multiplied by the distance to the dynamo in feet. Draw a straight line through this point, and the zero point. Similarly, draw the other radial lines corresponding to the other percentages of loss to be used, which can be done best by dividing the horizontal distance from the first line to the zero line into ten parts, and drawing a radial line through each one, thus each will represent one per cent. loss, as shown. If greater loss of potential is allowed, the corresponding lines should also be drawn. It is then ready for use.

To use it, multiply the number of lamps by the distance, find this number on the horizontal scale and follow it to the radial line which represents the percentage of loss; the cross-section, diameter, or gauge number is then found directly from the numbers in the vertical columns corresponding to the position of this point.

Such a graphical method will be found to save very much time, particularly when it is desired to make the estimate for several different systems of distribution, in order to find the most economical one. It is free from the errors which are liable to occur in tables, and takes only a very short time to prepare. Its range may easily be made very great, thus corresponding to a very large set of tables, which would require much time to prepare.

The point for determining the radial line should be chosen as far from the zero point as possible, in order to locate the line as accurately as possible.

In order to increase the accuracy for a small number of lamp-feet, that is, for the small distributing wires, a second horizontal scale of smaller numbers may be laid off, say at the bottom, and a second set of radial lines, drawn say in a different color, may be determined for these numbers. For still other ranges the cross-sections may be supposed to represent 10 or 100 times those in the column, and the corresponding scale of lamp-feet be found for the radial

Digitized by Google

lines already drawn, in which case the figures should be marked in a distinct color in order to avoid confusion. In that case the diameters and gauge numbers will no longer correspond with those new cross-sections.

GRISWOLD'S TORPEDO-BOAT.

BY GEO. H. REMINGTON.

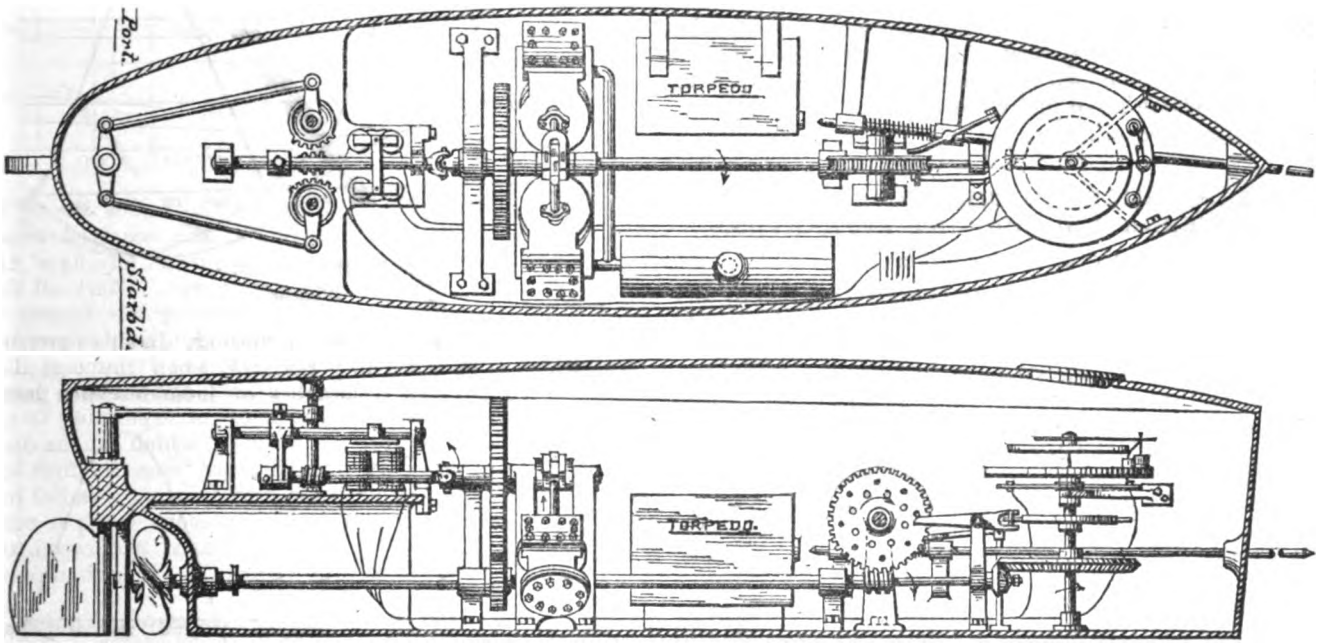
An exhibition of Griswold's torpedo-boat was given before a party of gentlemen, at Providence, R. I., a short time ago; the larger proportion of the spectators being manufacturers, mechanics and engineers, who were capable of comprehending the mechanical construction of the invention.

The boat, or rather model, is about six feet long and eight inch beam, made of copper and having very fine lines, in fact it is modeled from one of the government's torpedo boats. The deck is glass-covered and water-tight, rendering the interior mechanism visible. In service the boat is designed to be submarine—the inventor, Mr. Horace P. Griswold, of Providence, having devised an arrangement for automatically maintaining it at any depth to which it may be gauged—although the model has a free-board of about three-fourths of an inch. A six-cell battery, carried amidships, furnishes the power required for propelling and steering. What appears to be a very novel feature of the invention is the automatic steering arrangement, which consists of a compass having a finger adjustably secured thereto, engaging a light vertically-forked two-arm lever pivoted to and carried by a disc secured to a spindle adapted to be intermittently revolved. Each end of the two-arm lever being adapted to engage a small mercury cup, from which conducting wires electrically connect with magnets placed astern near the rudder. The armatures of the magnets are secured to a rod, supported in bearings, from which depend two arms, carrying a continuously revolving shaft, having a worm thereon adapted to engage wheels mounted on either side, which in turn connect with the rudder. Now, if the boat varies from its true course, the movement of the compass (being the natural magnetic attraction) causes the corresponding arm of the lever to engage a mercury cup, and instantly excite the steering magnets, thereby attracting the armature and swinging the revolving worm into connection with the corresponding wheel, and causing the rudder to move in the desired direction to resume the course. As the boat becomes "steady" the arm of the lever is automatically withdrawn from the mercury, thus breaking the circuit.

The movement of the intermittently revolving spindle, before referred to, is effected by pins mounted in a continuously (but slowly) revolving wheel, combined with an escapement lever, engaging overhanging pins adjustably mounted in the disc. This part of the invention constitutes the manner of pre-arranging the distance and course the boat is to take. That is to say, the angular distance between any two pins represents, say, 100 yards, while the angular distance between the pins of the disc of the compass represents the degrees in which the boat is to turn.

At the trial the first course selected for the boat to run was a quadrangular one, substantially the same as the diamond of a base ball field, each side thereof being about 100 yards.

After setting the several pins, both for angles and distance, and switching on the main current, the boat immediately started on its course (which was diagonal, and substantially south, east, north and finally west, to the starting point), its rate of speed being equal to that of a person walking rapidly. During the entire run no deviation whatever from a straight line was perceptible, except at the angular turns which were very short.



The boat at the termination of the run actually struck the wharf within *two feet of the starting point*, without doubt a feat never before accomplished; it being remembered that the boat had no connection whatever with the shore throughout the run; the whole being self-contained and the movements automatically made and controlled.

The next course selected was south-west about 150 yards, turning 180 degrees, and running about 100 yards, again turning 180 degrees and running south-west about 100 yards, and finally turning 180 degrees, and running back to within a few feet of the starting point. Several prominent gentlemen, including Hon. Henry J. Spooner, M. C., having arrived during this run, a request was made that the first course be repeated, which was done, and the boat returned to within a *few inches* of the starting point.

After making another single run out, of about 250 yards, and returning, the trial was concluded. The universal expression of those present was that the boat had accomplished an unparalleled feat in thus going out from the shore and returning thereto without being in the meantime assisted or controlled in its action from without.

Mr. Griswold states that in practical use the boat will be made about 18 feet long, and arranged to carry a torpedo

Digitized by Google

or explosive charge which is to be electrically fired by means of a firing-pin projecting from the bow of the boat coming in contact with the hull of an enemy's vessel, in which case the torpedo-boat as well as the enemy are destroyed.

In case, however, the boat should fail to meet an obstruction, it returns to the station—which may be a war vessel. Just before its arrival, a device automatically locks the firing-pin in position, thus rendering the boat safe in handling. At the same time a float is automatically released and the electric current or other motive power cut off, thus stopping the boat's progress.

It is almost impossible to conceive of the advantages possessed by this auxiliary to naval warfare.

The cost of the improved torpedo-boat is small compared with those now in use, and which are controlled by means of electric currents passing through a cable connected with the shore or station, and the boat.

In view of the reduced cost it has been suggested that a surface boat provided with the self-steering and propelling mechanism might be employed in exposed places along the coast by the light house and life saving stations, to communicate with the shore or with stranded vessels during the weather that the crews consider extra hazardous.

Mr. Griswold is to be congratulated upon so successful an exhibition of his invention. He certainly is deserving of great praise for his persistency in working out the problem in spite of many obstacles, and in the face of ridicule, and it is to be hoped that he may, ere long, meet with the reward which he so justly merits.

PROVIDENCE, R. I., November 13th, 1886.

THE MEASUREMENT OF THE POWER ABSORBED BY ALTERNATING CURRENT APPARATUS.[1]

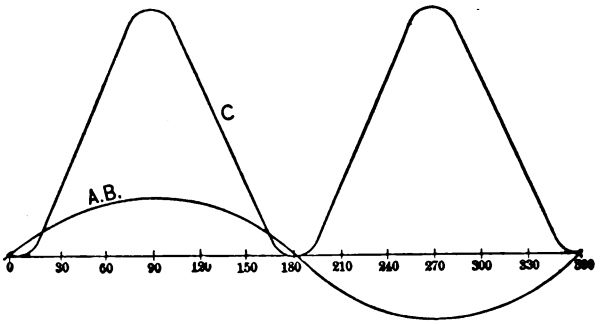
BY M. HOSPITALIER.

WHEN we wish to determine the power absorbed by any electrical apparatus whatever, the simplest method is to measure the difference of potential in *volts* at the terminals of the apparatus, and the strength in *amperes* of the current passing through it: the product of these two quantities gives the electrical power absorbed in *watts*.

This method, which is exact when we are employing currents that are continuous or practically continuous, such as machines called continuous current machines, in which the variations of strength may be disregarded, is subject to certain reservations when periodical currents are used, especially in the case of alternating currents, and when the apparatus expending the electrical energy is the seat of more or less complex reactions from induction. In this case, the product of the indications of a Siemens electro-dynamometer by those of a Cardew voltmeter does not *a priori* give any reliable information as to the electrical power really expended, which may vary between a maximum, limited exactly by the product of the indications of the two measuring apparatus, and a minimum, the theoretical limit of which is zero.

The following diagrams are intended to show this clearly:—

Let us first consider a periodical electromotive force, sinusoidal in form, so as to simplify the reasoning, established between the terminals of a conductor, the co-efficient of self-induction of which is 0, or may be disregarded. The strength of current will be given each moment by the ratio of the electromotive force to the resistance of the circuit. By choosing the scales and the resistance of the circuit to suit our purpose, the numerical values of the current, I, and the electromotive force E, will be equal at each moment. If we take a complete period, and express on a diagram the time in abscissæ and the values of I and E in ordinates, we shall get two sinusoidal curves blended in the fine line of figure 1. The electrical power expended each moment will be equal to the product, E I, *i. e.*, to the square of E or of I, and represented by the thick curve of figure 1. The work absorbed during a complete period will

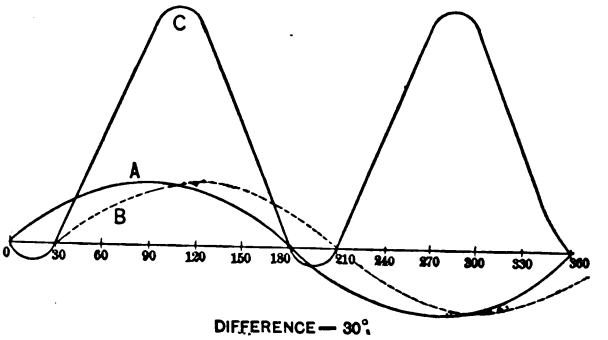


DIFFERENCE— 0° CONDUCTOR WITHOUT SELF-INDUCTION.

Fig. 1

be represented by the *positive surface* comprised between the axis of x and the two thick curves, figure 1.

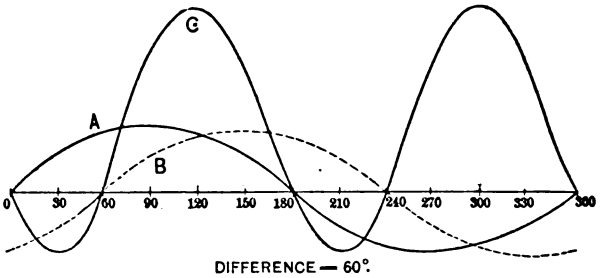
The *mean* power corresponding will be the ratio of this



DIFFERENCE— 30°.

Fig. 2

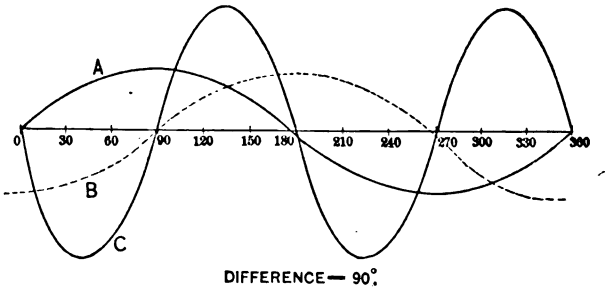
surface to the duration, t, of the period. In this particular case, which is very sensibly realized when the periodical current feeds inert resistances or incandescence lamps,



DIFFERENCE— 60°.

Fig. 3

there is no difference between the value of the mean electrical power actually expended and that which results from the product of the indications of the voltmeter and the



DIFFERENCE— 90°.

Fig. 4

electro-dynamometer. Let us now substitute for the ordinary resistance an apparatus presenting self-induction and mutual induction, such as a transformer.

1. From *L'Electricien*.

Digitized by Google

Theory shows that in this case there arises a *difference of phase* between the intensity of current, I, and the electromotive force, E, and that this difference may vary from 0° when the co-efficient of self-induction of the apparatus is 0 to a maximum of 90°, a theoretical limit which is never attained in practice. The determination of the exact value of this difference is very difficult, for it depends on the duration of the period, on the co-efficients of mutual induction, and of self-induction in the inductive and induced circuits of the apparatus to be measured, on the presence or absence of an iron core, of the greater or less magnetic saturation at the moment of the maximum current, &c. Experiment alone can make us acquainted with the value of this difference for every condition of working the circuit; but we may ascertain its influence by constructing curves corresponding to some of the special values that it may have. This is what has been done in figures 2, 3 and 4, which correspond respectively to 30, 60, and 90 degrees, supposing, be it understood, that the conditions of working the machine have been modified so as to preserve the same mean numerical indications for the strength of the current, I, and the difference of potential, E, at the terminals of the apparatus to be measured.

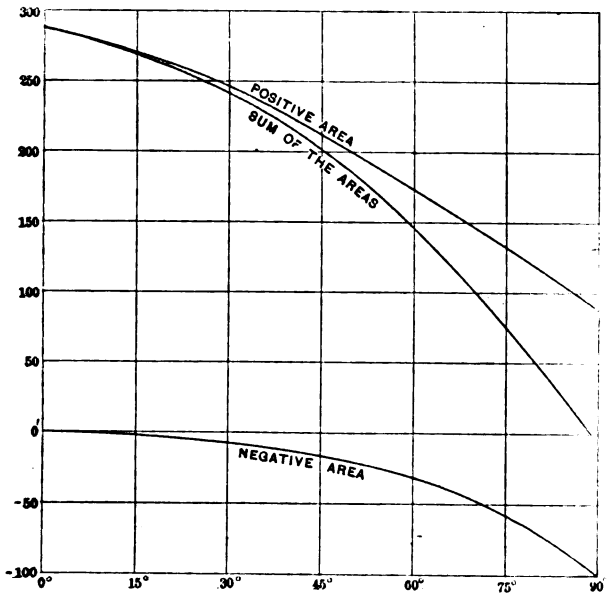


DIAGRAM OF ELECTRICAL POWER IN TERMS OF THE DIFFERENCE.

Fig. 5

In the three cases under consideration we see that the curve representing the power has two negative portions, which involve not an expenditure but a restitution of energy stored up a moment before in the reactions from induction.[2]

The positive area representing the work expended diminishes, whilst the negative area representing the work restored increases. This action, hardly appreciable with a difference of 30 degrees becomes pronounced with one of 60 degrees. At the theoretical limit with a difference of 90 degrees, figure 4, the two areas, positive and negative, are exactly equal, and the total work expended during the period is equal to zero, although the indications of the voltmeter and the electro-dynamometer remain constant.

Figure 5 sums up these results. The values of the difference are carried out in abscissæ, and the ordinates show the respective values of the positive work, the negative work and the algebraic sum of the two for a complete period.

This figure shows the great importance of this difference from the point of view of the difference between the electrical power really expended and that obtained from the product of the indications of the instruments of measurement.

For a difference of only 30 degrees the difference between the work really expended during a period and that deduced from the indications of the measuring apparatus would exceed 15 per cent.

Thus there remains much to be said about the power and the rendering of transformers, and, in general, about all apparatus supplied by periodical currents.

2. The effects thus produced may be compared, by analogy, to those of a flywheel mounted on a machine, the speed of which is irregular. The successive storages and restitutions of energy weaken the variations without involving any loss.

DYNAMIC ELECTRICITY.

BY CARL HERING.

(Continued from page 453, vol v.)

CHAPTER V.

ARMATURES.—(*Concluded.*)

CYLINDER armatures differ from the Gramme principally in the following respects. Their advantages over the latter are: for the same magnetism in the field the volume of the armature, and, therefore, also the size of the dependent parts of the rest of the machine, is smaller, owing to the lost air space in the inside of the Gramme ring; the proportion of the wire on the armature which is active, is greater, that is, for the same field, electromotive force, current, and inductor velocity, the amount of wire required on the armature is less; for the same capacity of armature, the internal resistance is smaller; when thick wire is used for the windings, it is more easily handled than in the Gramme; it is easier to fasten the core rigidly to the shaft, without the loss of valuable wire space around the core; they are more easily centered or balanced accurately for high speeds; the core, if made of sheet metal, is less expensive, as there is less waste; an unbalanced field, that is, one in which leakage or other causes make one pole stronger than the other, will affect it less than it would a Gramme ring.

The disadvantages are: it is more difficult to insulate the wires for high potentials, as two neighboring wires may have the whole difference of potential of the machine in them; a high inductor velocity is not so easily obtained without great increase of weight of armature, as its weight increases with the square of the diameter, while in the Gramme it increases merely as the diameter; if one coil burns out it will often necessitate the unwinding of several others, or even of all the others, as the injured one is frequently among the first or inside coils; it is almost impossible to have all the coils symmetrically situated and of the same length; for the same cross-section of armature core, it presents less external surface for the induction wires; it is more complicated to wind properly, and therefore requires a more skilled mechanic.

In designing cylinder armatures the following points are the most important, besides those already given. The greater the length as compared to the diameter the greater will be the proportion of active wire. On the other hand, the greater the diameter the higher will be the inductor velocity, which it is desirable to make as great as practicable. Both diameter and length should therefore be made as great as practicable; but as a practical limit is soon reached, it is necessary to determine by trial calculations for each special case, which of the two advantages has the greater weight. For high potential machines in which a slightly greater amount of dead resistance is not very objectionable, the diameter might be increased, while for low potential, quantity machines, the amount of dead resistance is of more importance, and therefore it might be better to increase the length of the core. As other considerations may however have greater weight in special cases, no general rule can be given.

The coils should all have as nearly as possible the same length and resistance, and should all be symmetrically situated with respect to the field and to their mean

Digitized by Google

distance from the centre of the shaft. The difficulties of accomplishing this is comparatively great, and it is therefore of the utmost importance to guard against irregularities of winding, for, as stated before, if the electromotive force induced in one half of the armature is greater than that in the other, even if only a small amount, a current will circulate, on open circuit, in the armature wire itself, which by Ohm's law is equal to this difference of electromotive force divided by the resistance of the wire, and as the latter may be very small, this wasted current may be quite great. On the other hand, if the inductions in the two halves are exactly equal and the resistances unequal, the differences of potential at the ends of the two halves (that is, the total electromotive forces, less that absorbed by the armature wire itself) will be unequal when the machine is running with a load, and there will be irregularities or pulsations in the current which may increase the sparking.

A coil should not be too wide, measured along the periphery of the armature, in order that the coil which is short circuited by a brush may be entirely in the neutral part of the field. The real neutral field is always considerably smaller than the distance between the pole piece projections. The coils should, for the same reason, be wound so that the two sides are as nearly as possible diametrically opposite to each other, though they need not be exactly opposite.

As the wires have to cross over one another at the ends of the armature, they occupy considerable space there, and make what is termed the "heads." It is evidently well to make these as small as possible, for several reasons; it shortens the shaft and the distance between the bearings thus decreasing the width of the machine; it shortens the bearing braces or supports and reduces the tendency to vibration as the shaft is thereby stiffened; it makes the length or resistance of the different coils more nearly equal, as the lengths gradually increase from the lowest, or first coil, to the last, and with large heads this increase is evidently considerable; a small head is more likely to be flat, therefore diminishing the tendency of the wire to slip off and loosen the coil; it will facilitate making the windings compact and solid to have a small head. In order to reduce this head, the number of windings should be as small as practicable; the number of crossings should be as few as possible, and the turns of one coil should therefore be parallel and not cross over one another; the wires of the head should be bent around so as not to bring several crossings over each other, that is, the crossings should be distributed over the head so as to keep it as flat as possible. When wires at the head are unavoidably in such a position as to be likely to slip, they should be tied with strong twine or tape, in order to hold them securely in their places. All wires crossing each other should be particularly well insulated with tape, shellaced muslin, fibre, or dense shellaced cardboard which is not likely to break.

The general principle of the cylinder winding is as follows. If, as in figure 16, a cylinder be supported on its axis, and while turning slowly, a wire be wound over it lengthwise, it will, after having made one complete revolution, be wound with the simplest form of a cylinder winding. To complete it, the end of the wire must be connected with the beginning to make it an endless wire, and the beginning of each turn, or number of turns forming a coil, must have a branch wire attached to it for connecting it to the commutator, as shown by the bold lines.

In continuing the winding shown in this figure, it will be found that after a few more turns the armature will be completely covered with the wire, while the winding has been continued for only one-half of a revolution of the cylinder. Furthermore, the commutator branch connections will be found to be along only half the circumference, while the beginning and end do not meet and cross, but are parallel and in the same direction, so that they cannot be joined properly. This is often misleading and confusing to any one winding a cylinder armature for the first time, as it gives the impression that there is some mistake. It will be easily understood if we remember that the winding must be continued for one complete revolution of the cylinder, and as it is entirely covered after half a revolution, it follows that in the second half revolution the wire will have to be wound over that already on the cylinder, thus making two layers over the whole surface.

This simple form of cylinder winding has the objection that the coils of the second half are longer and larger, having a greater mean radius and, therefore, a greater

Fig. 16

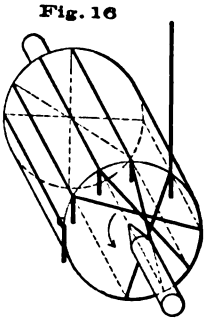

Fig. 17

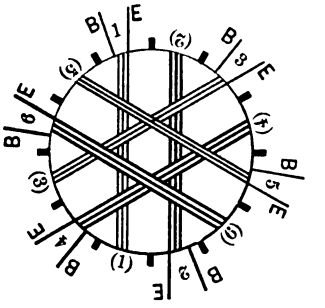
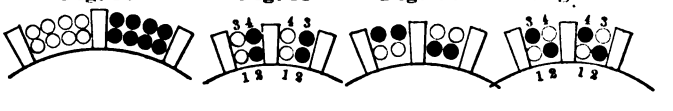


velocity, as they are wound over the others. This, as stated before, is a fault which should be avoided, if possible. It can be overcome to a great extent by dividing the surface of the armature into the proper number of sections, as shown in figure 17, and winding at first only in every alternate section, until half of the whole number of coils are wound, as shown in light lines, and then continuing the winding of the rest of the coils in the remaining alternate sections, as shown by the dark lines. All the coils will then be symmetrically situated, will have the same mean radius, and more nearly the same length. This method will answer very well when there are numerous turns in each coil, or in general when the width of the cross-section of a coil is greater than its depth, as shown in figure 18, in which the dark and light sections represent the neighboring coils which belong to diametrically opposite commutator bars, as shown in figure 17. This proportion of the sides of the cross-section will generally be found to exist when the number of coils or commutator bars is small.

In the better class of machines this is however not generally the case, as for instance, when there are two turns per coil, for then the depth is greater than the width, as shown in figure 19, and there may be difficulty in keeping the coils from collapsing while they are being wound. The method shown in figure 20, is often resorted to in such cases, but it is not to be recommended except when there are very many coils or commutator bars, as they have different mean radii from the axis. The difficulties mentioned have all been overcome by the ingenious method

Fig. 18 Fig. 19 Fig. 20 Fig. 21



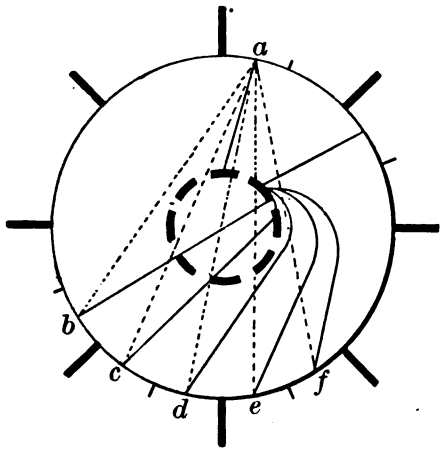
devised by Weston, and shown in figure 21, in which each coil is split into two equal parts, which lie alternately over and under the corresponding parts of the other coil belonging to the diametrically opposite commutator bar. In this method the turns are wound in the order as indicated by the numbers, either as in the first section or as in the second, the latter being less confusing while winding and the former simpler to the experienced winder. The advantages of the Weston system over the others increases with the number of turns per coil, and decreases with an increase in the number of coils. In the method in figure 19, the order of the winding may be either as shown by the numbers in

Digitized by Google

the first section, or by those in the second; the former is less confusing, while the latter is simpler.

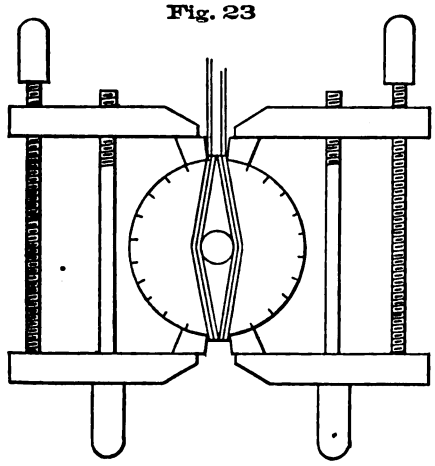
Referring to figure 22, which shows an end view of the unwound armature with eight sections, each for two coils belonging to opposite commutator bars, if we start at the first upper commutator bar, and wind into the first section *a*, we may return to the face in any one of the opposite half-sections *b*, *c*, *d*, *e*, *f*, thence to the next bar and the next but one half-section as shown. By returning in the diametrically opposite part *d* it will be the old Siemens winding, which, as will be seen by completing the winding, is slightly irregular.[1] By returning in *e*, or *c*, it will be the Froehlich or Breguet, which are practically identical; both

Fig. 22



are quite regular. By returning in *b*, or *f*, the winding becomes very irregular and should not be used. If the number of coils is odd, the Froehlich and the Breguet systems merge into one, that is, the half-sections *e* and *c* become one and the same, being then in the position of *d*, diametrically opposite to *a*. This is known as the Edison system. The Weston system is the old Siemens improved by splitting the coils as described. The writer's system is this same principle applied to the Froehlich, and is, therefore, quite regular and symmetrical. The chief advantage of the Froehlich over the Siemens, besides its regularity, is, that there are only half as many crossings of the coils on the ends, thus making smaller heads.

Fig. 23



When iron lugs or projections are used between the coils, the winding becomes less difficult. In that case each layer in one section (which may embrace from one to five or six coils) should be completed before the next layer is wound, thus frequently necessitating a number of coils being wound at the same time; or, if this is confusing, a pair of wooden blanks should be made of exactly the width of the vacant part of one section, and be fastened there until the coil is completed and bound with tape.

When there are no lugs or projections of the core, the surface of the armature should be carefully spaced off into the required number of sections. It will then be found convenient, if not essential, to make wooden blanks of exactly the width and shape of the section of a coil, and clamp them as shown in figure 23, leaving a trough of the exact width of one coil. In this case, it is advisable to wind first every alternate section and bind the finished coils with tape, in order to leave vacant spaces for inserting these wooden guiding blanks. When the armature is half wound it will present the appearance of a cogwheel, with a trough between every two sections; these troughs being of exactly the width of a coil, are then readily wound with the remaining number of coils.

In winding the simple form shown in figure 17, in which each coil occupies the whole depth, proceed as follows: Suspend the armature core with its shaft on two high lathe centres, or on two similar centres between two strong posts, and jam it so tightly that it requires some force to revolve it. Select from figure 22 the method which is to be used; divide the armature surface into the required number of sections and mark on it, with the same number or letter, the two opposite sections which are to contain the first coil; similarly for all the others as in figure 17. Then, if there are partitions between each of the coils, as in figure 17 or 18, start at the upper section No. 1, and wind one coil, connecting its end temporarily with its beginning, and marking them, if desired, B and E. Then turn the armature around half a revolution, and starting in the same way wind the neighboring coil No. 2, figure 17, precisely similarly, connecting its ends together and marking them as before. Then turn the armature again for half a revolution and wind No. 3, and proceed thus, turning the armature one-half a revolution after each coil is completed. When it is completed, there will be a regular series of beginnings and ends of coils along the periphery of the armature, and they will all be in their proper relative positions. Untie the ends and connect the one marked E (end) of any one coil with the *next* one marked B (which will be in the next but one section) and with one commutator bar; the one marked E of this coil connect with the next B, and so on. By winding it as described it will be found to be almost impossible to make a mistake in the connections or in the proper location of the coils belonging to different sides of the commutator.

Another method is to wind first, sections 1, 3, 5, etc., figure 17, *without* turning the armature through half a revolution each time; then winding the even numbers, beginning at the point marked 2. But this is not so good, as the distribution of the unequal resistances of the separate unequally long coils is not so well balanced as in the first method. When the heads are small this difference will be less.

In winding the coils as in figure 19, two coils should be wound at the same time. Cut two wires to the proper length, call one the light wire and the other the dark. Start with one turn of the light wire (marked 1), fasten it, turn the armature through half a revolution and start the first turn of the dark wire (marked 2); turn the armature again and wind the turn No. 3 with the light wire which completes that coil; turn again and wind the turn No. 4 with the dark wire, which completes that coil. If the order given in the second section is to be used, the only difference is, that the armature is not turned between windings 2 and 3, which are taken with the same wire; neither is it turned in that case, between winding 4 of that section and 1 of the next. In the first method it must be turned between every two windings whether they be both in one section or in two neighboring sections.

If there are no lugs, and the appliances in figure 23 are used, in which case every alternate section should be

1. A detailed discussion of these forms of windings will be found in the ELECTRICIAN AND ELECTRICAL ENGINEER, March 1886, p. 84.

Digitized by Google

wound first, it is evident that if the winding in figure 18 is used, the armature should *not* be turned after completing a coil, as all will then be "light" coils until half of the coils are completed; in the winding shown in figure 19, however, in which each section is a complete set of two coils, proceed just as if there were no alternate section omitted.

If the Siemens winding, or any of its modifications are selected, it must be remembered that there is a slight irregularity just after completing the winding of half the number of coils. If this is not noticed it may result in wrong connections or in the unwinding of some coils, or in objectionable cross connections. In the Froehlich winding it is necessary to guard against winding into the wrong sections, as they are not diametrically opposite. In all cases errors are easily avoided by making a correct drawing first, numbering the sections and transferring these numbers to the armature core.

If by accident a coil has been wound in the wrong direction, provided its location is right, there is no necessity to unwind it, as it will answer just as well to connect it as if the beginning were the end, and the end the beginning. This applies to Gramme armatures also.

To examine an armature for wrong connections of the beginnings and ends of coils, which should always be done, place the armature north and south, put a small compass needle off to one side of it, about on a level with the axis, and test each coil as it comes into the vertical plane, with a tolerably strong current, by touching the two upper commutator bars, or the two upper connections. The compass should always deflect in the same direction. If it changes its direction of deflection, reverse the connections of that coil. It is not necessary to disconnect the commutator for this test, if the current is strong enough.

UNIPOLAR ARMATURES.

The term unipolar as applied to machines, has not reference to the polarity of the magnetic poles, as lines of force always have direction, and therefore two poles. It has reference, we presume, to the polarity of the armature which in such machines is always in one and the same direction, not reversed twice in every revolution, as in ordinary machines. The advantage thereby gained is that the currents will always be in the same direction in the armature coils, and it is therefore not necessary to have a commutator to cut out and reverse the connections of a coil just as it passes out of one field into the other, that is, just as the induced current in it will be reversed, as in ordinary machines. All sparking is therefore avoided, as the circuit is never opened or altered in the machine itself. All the evil effects of self-induction are also avoided, as there is no continued starting, stopping, and reversing of current in the armature coils. The current from such machines is precisely like a battery current, free from the pulsations always accompanying ordinary machine currents. A telephone connected to a fine wire coil, which forms the most sensitive detector of pulsations in currents, fails to detect the slightest variations.

Strange to say, the unipolar machine in the form of Faraday's disc, was, we believe, one of the first electric machines for currents ever invented; yet it has not until quite recently been made efficient to generate a current of more than a very low potential.

The difficulty encountered in the old forms of unipolar machines was that the lines of force of the field could be cut only once by the inductor or armature, and that to obtain a potential greater than a volt or two, it was necessary either to increase the speed, intensity of field and size of armature to an impracticable degree, or else to couple a large number of machines in series. In the ordinary bipolar machines, the inductor is in the form of a coil, and therefore cuts the same field a great number of times in one revolution, generally over 100 times, thus making the potential over 100 times that obtainable from a unipolar machine with the same field and inductor velocity.

Siemens improved the unipolar machine, by making the armature a tube with a cylindrical pole inside and a hollow pole outside having the opposite polarity. The lines of force passing from one to the other are cut by the revolving tube, thereby generating a current in one direction in the tube, which was collected at the two ends. In this machine the pole areas were quite large, but it is evident that this does not increase the magnetism more than a very little, unless the magnets themselves are increased also. With such a machine about two volts were generated in a tube several feet long. The current, which is limited only by the resistance opposed to the two volts, was naturally very great, being, we believe, several hundred amperes; the armature resistance is, of course, very small, the greater part being in the collecting brushes.

Forbes' improvement consisted in making an economical field of very great intensity and rotating a disc between the poles. Two such discs in two independent fields constituted a machine. The discs were of iron to increase the magnetism. The polarity of the two fields was such that the current was from the periphery of one disc to its centre, and *vice versa* in the other disc, in order to enable them to be connected in series by the shaft. The current was collected at the periphery of the two discs by numerous brushes. With two 10-inch discs this machine gave at 3,000 revolutions, about 5.5 volts on open circuit, and about 2.5 volts when giving over 3,000 amperes. If the internal resistance had been lower this fall of potential would not have been so great.

The difficulty in unipolar machines is to connect several discs, bars, or wires of one armature, in series with each other, that is, to make the same inductor cut the same field a number of times. In England, France, and Germany, numerous patents have been granted for such machines in which this difficulty was supposed to have been overcome by connecting the end of one of the bars or wires of the armature, permanently to the beginning of the next by a wire, thus connecting them in series. This, however, will evidently not generate any useful electromotive force, as this connecting wire must in all cases in which the connection is permanent, also cut lines of force, and exactly the same number which the inductors cut, but unfortunately for the inventors this induction must necessarily be in the opposite direction, thus completely neutralizing the other electromotive force induced. It has been suggested to make this connecting wire pass through a weaker field, thus allowing the difference of the two opposing electromotive forces to appear at the brushes. This is also inoperative because wherever the same lines of force make a less dense field, it must be larger in area, that is, it has the same number of lines of force. It has been suggested to shield these wires by an iron tube, but as this tube also cuts lines of force, they must also pass through its centre, that is, through the wire.

A machine was devised consisting of a Gramme ring without a commutator, the wire being cut in one place and led to two collecting rings. One pole completely encircled the outside of the ring, while the other, a revolving pole, was permanently connected to the iron of the ring by arms extending in between the coils. The ring was then rotated. It was supposed that the lines of force would pass out of the core between the wires, and thus would not be cut in the reverse direction by the same wire. But as might be supposed the lines of force did cut the wire in two opposite directions. In a small model constructed some years ago by the writer, not the slightest current could be detected even by a sensitive galvanometer.

Faraday's suggestion was to revolve two discs in the same field, in opposite directions, and then connect the two peripheries together by sliding contacts. The two electromotive forces will then be in the opposite direction in the two discs, but in the same direction with reference to two

Digitized by Google

collecting brushes at the centres of the discs. This will overcome the difficulty, but for more than two discs it becomes impracticable.

Within the last few years a number of unipolar machines have been invented, in which any number of armature wires or bars, may be connected in series with each other, that is, the same field may be used a number of times by repeated inductions in the same circuit. The principle is that the current is led off at the end of one inductor by a sliding contact and by a wire which is fixed with regard to the field, and therefore does not cut lines of force ; this wire is connected to the beginning of the next inductor by a sliding contact, and so on, connecting them all in series. By this means any desired electromotive force may be induced, while the current may be very great owing to the large and short inductors which may be used.

ALTERNATING CURRENT ARMATURES.

In the general type of alternating current machines the armature consists of a series of coils or turns of wire in one plane, generally placed in a circle at the circumference of a disc which is rotated. On both sides of these coils are a series of fixed field magnets with their opposite poles toward each other thus making a large number of independent fields through which the coils of the armature move when the disc is revolved. The field magnets being so connected that the polarity of each field is in the reverse direction to that preceding, the currents in the armature will be reversed continually as the coils pass through the successive fields. The armature coils are permanently connected with each other, the two terminals of the whole series being connected to two insulated rings on the shaft, on each of which a brush rests for collecting and leading off the current. The armature coils may be with or without iron cores ; in the former case, the induction will be much greater, but the iron heats so much that it is usually omitted. All iron cores, even if carefully laminated, will heat if encircled by an alternating current.

Such an armature possesses the great advantage that the coils may be connected in multiple arc, in series, or in any combination of groups, thus permitting the same machine to be readily altered to give a low tension and large current, a high tension and small current, or any intermediate grades that can be obtained by possible groupings of the coils.

The other, and perhaps chief, advantage is that the current is not commutated, and that therefore no commutator is required, thus avoiding all sparking, wearing off of brushes and commutators. No setting of brushes is required, as there is no neutral line to which they must be set.

A curious feature of some alternating current machines, and perhaps of all of them, is that they require more power when running on open circuit than when working with their normal load, and that consequently the machines will get very hot on open circuit. On the other hand when they are short circuited they run light, that is, require very little power to turn them. If an armature coil is to be cut out it should be short circuited and not left open as in constant current machines. The explanation of this is, probably, that the counter induction in the coil is so great when short circuited that it is almost equal to the initial induction, and that, therefore, only the difference between the two will act to generate a small current in the coil.

In the large Gordon alternating current machine the position of the field magnets and the armature are reversed. The field magnets are on the circumference of a large flywheel, eight feet in diameter, and are made to move past the armature coils which are fixed to the frame on both sides of the magnets. The great advantage of this is, that the armature coils may be disconnected, short circuited, or grouped in any desired combinations while the machine is running. The coils are generally connected in two groups giving two currents which can be used independently of one another. Regulation may be effected either by varying the field current or by short circuiting some of the armature coils.

In general, alternating current machines must have a separate exciting machine for the field magnets, as these require a constant current ; this is, of course, a great objection to their use. In some, however, the current from a few of the coils in the armature, is commutated, so that it becomes a constant current which may then be used for the field.

The great objection to alternating currents, is the self-induction of solenoids and particularly of magnets. For this reason any shunt solenoids or magnets used in regulators or cut-outs, as in arc lamps, must be made very large in order to have the same power or pull. Any iron used in connection with them must be limited to a small quantity and must be well laminated, or it will heat very much. A core for such a solenoid may be made of a roll of ferrotype iron. The counter electromotive force in a solenoid for alternating currents is not a constant quantity like the resistance, but depends also on the number of alternations, that is, on the speed, and on the current ; it will, therefore, vary under any but the perfectly normal conditions, and for this reason, it cannot be depended upon in automatic regulators, meters, and in most measuring instruments, except when coils with very few turns, or in general, series coils, are used, as distinguished from fine wire or shunt coils. Such currents may be measured with an electro-dynamometer, and potentials with some voltmeter without coils, such as the Cardew, which depends on the expansion of a wire heated by the current.

Motors may be run with alternating currents, but it is not advisable nor economical to do so.

(*To be continued.*)

WHAT IS ELECTRICITY ?—A SUGGESTION.

BY FRANK M. MILLER.

In the autumn of 1885, a gentleman of this city, called my attention to a chemical compound which he thought possessed characteristics useful for electrical purposes. To discover its salient qualities an investigation was first directed to its specific resistance. With the apparatus at our disposal it was found that its resistance was phenomenally high ; in fact the apparatus could not measure it, and it remained unknown as it does to this day. Of course, current will pass through the compound and the galvanometer needle will show a slight deflection, but to use the language of a well-known electrician, who also tested it, "it is the poorest known conductor."

This discovery was both novel and suggestive, and the compound was looked upon as something remarkable ; but with this reference that subject will be dismissed, and the line of thought and research that was suggested by the phenomenon will be set forth.

Knowing that all matter is dominated by law, it was logically concluded that this phenomenon was the expression of a law that, so far as the authorities go, was and is unexplained ; therefore, we were thrown upon our own resources for an explanation. As my friend knew exactly what the elemental substances were of which the compound was formed, and taking each in turn to solve the problem only to find that that was not the agent, he at last came to the conclusion that the hydrogenous richness of the compound was unmistakeably the agent, and he at once declared that the reason for the high resistance was, that the compound contained a large volume of hydrogen, and that hydrogen was and is the true electrical resistant.

Succeeding this declaration, in examining a treatise upon chemistry, I noticed this remarkable fact, that in a list of hydro-carbons those having the largest volume of hydrogen were of the highest electrical resistance, or in other

Digitized by Google

words, that the electrical resistance was proportional to the volume of hydrogen. This was conclusive proof to my mind, and the facts are indisputable and patent to all observers, while any chemical treatise upon the subject substantiates the hypothesis, and the hydro-carbons themselves, with galvanometric tests of the same prove it; for as the characteristics of carbon are well known, the hydrogen alone remains to explain the fact, and its varying volumes and proportional resistances claim acquiescence to the hypothesis.

The remark will be made that this may be true of chemical compounds, but it does not explain the phenomenon in its relation to the metals. This can be answered so soon as it is known what the metals really are. To say that they are undecomposable substances, or elements, expresses no fact upon which to base a proposition or formulate a denial. The phenomena of occlusion or the absorption of gases by highly heated metals give a partial answer and seems to show that the electrical resistance of matter is dependent upon molecular structure. But a step further may be made upon the assumption that the so-called sixty odd elements may be—and surely no one would hazard a positive "no" to this hypothesis—but compounds that are combinations of a few primary elements. This has been suggested long since, and if true, it is certain that the unit element would be found as a primordial, and therefore upon this hypothesis, those metals of highest electrical resistance would be found to contain large volumes of hydrogen, and those of greatest conductivity, to contain elemental substances for which hydrogen has greatest affinity; but until there is positive knowledge in this branch of metallurgy, the question remains an open one; but with what is known, the hypothesis may be made that hydrogen is the true electrical resistant, and that instead of molecular structure dominating the electrical resistance of matter, it is probably dependent upon the volume of hydrogen which the matter contains.

Electrical resistance thus defined is a question of chemical reaction. This at once broadened the research and led on to an investigation of the force which overcomes the resistant, or to electricity itself; and having made satisfactory progress in the solution of that problem, I will explain the result; but first I would remark that my friend, A. de Figanière, gave this part of the work to me, while he carried the work on into the domain of magnetism and crystallization which naturally followed the discovery of electricity.

So far as I know, the question: "What is electricity?" has been met with only intangible answers and vague surmises, or it has been relegated to the category of those other potent but unknown forces, heat, light, and motion. That it exists is self-evident; that it is *some* thing, is a sequence of its existence.

To approach the enigma let us take the voltaic cell, where by chemical decomposition we get the mysterious and evanescent thing called electricity.

Take the simplest form of voltaic cell, that of a piece of zinc and a plate of copper immersed in water, and upon joining the two metals with a length of wire an electric current is found flowing therein. Here are known things producing the unknown thing.

Allowing the cell to remain thus, we notice an accumulation of gases upon the surfaces of the metals, oxygen upon the zinc, hydrogen upon the copper. We further notice that by the addition of sulphuric acid to the water, an immediate and continuous decomposition of the zinc, a larger volume of hydrogen upon the copper plate, and more current. As the copper remains constant in its characteristics and volume, the decomposition of the zinc and the increase in the volume of hydrogen are the only features in the process, and they are both prominent and important, for herein is a repetition of a laboratory method generally used by chemists to secure a store of hydrogen. It is, therefore, evident, that the presence of the hydrogen upon the copper plate is the result of the decomposition of the zinc; thus that factor can be eliminated from the research. The oxygen of the water that is decomposed is found at the zinc while the hydrogen of the same but augments the store already found at the copper; thus the water is accounted for. Nothing now separates us from the current but the copper plate upon the surface of which free hydrogen is found, and flowing from it the current. If the copper (or piece of carbon if that is used) changed its characteristics in the process, the problem might be more difficult; as it does not, but remains constant, it, too, can be eliminated from the research. There is now left but the hydrogen upon the one side of the plate, and the current emanating from the other, and I reason that the decomposition of the zinc produced the hydrogen, which by the law of chemical affinity, flowed to the substance in the copper for which it has affinity (or to the element, as some may prefer to say), and is taken therefrom as an electric current, or that the hydrogen generated in the cell flows outside of it still as hydrogen, or in other words, that hydrogen is the electric current, and that it is evolved by and under the laws of chemical action and affinity.

I base this belief upon the hypothesis that if the factors zinc and sulphuric acid produce in the laboratory hydrogen, there is no reason why the electrician should not get the same result when he uses the *same* factors in the *same* combination; and that there is no reason why the electrician should not individualize the result of his process by the same nomenclature as that which the chemist uses. At present it is recognized that all chemical action first produces a current of electricity; but for a peculiar corroboration of the assertion above made I refer the reader to Attfield's Chemistry, a note on page 97, where specifying the results of this chemical reaction, he thinks it possible to construct an organization using these factors to give (at the same instant) the two manifestations of the same force. But for proof of the hypothesis I go to the oldest manifestation of electricity, *i. e.*, the thunder storm, wherein the elements best known generate that force. By excessive friction the watery vapor of the clouds is decomposed and the hydrogen is liberated, to instantly recombine with the oxygen to form water, with the consequent explosion and light and immediate downpour of rain. (It has passed into a common saying that a lightning flash is immediatly followed by heavier rain.) This phenomenon has remained unnoticed for ages, yet it is but another laboratory experiment on a grand scale, and in this instance, at least, it cannot be denied that hydrogen is electricity, and for remarkable corroborative testimony I refer to Sir William Armstrong's hydro-electric apparatus, where the friction of globules of water against wood is made use of to produce electricity.

Another natural phenomenon corroborates the hypothesis. It is a law that "electricity, flowing through a conductor, generates heat;" simply because hydrogen being a factor of combustion meets the other factors of combustion as it flows through the conductor, the result being the consequent heat; and if the conductor is cut in two, and these ends alternately open and close the circuit, a modified explosion immediately follows as the *hydrogen* unites with the element having affinity for it. Another natural phenomenon bears testimony to the truth of the hypothesis. In the effect which the aurora borealis has upon the magnetic needle and telegraphic instruments, it has been supposed that that was electricity, *per se;* but the nearest approach to discovery of its nature has been with the spectrum, which shows a green light exactly corresponding to the spectrum of the zodiacal light and the tails of comets. This is all that is known of these phenomena, and it will be asked what relation has this to hydrogen, the spectrum of which gives a red light. The answer to which is, that it is true the spectrum of hydrogen

Digitized by Google

gives the red light under certain conditions, but it is equally true that under other conditions it gives the identical green light of the aurora, and that when it gives the green light it is under low pressure, as also the aurora must undoubtedly be. I refer the reader to Wüllner's series of experiments with the spectrum of hydrogen, wherein he shows that under a pressure of less than one millimetre the spectrum was green.

This experiment shows that at a very low atmospheric pressure hydrogen is identical with the aurora, and at such low pressure it is certain that the expansiveness of the hydrogen has sundered the cohesion of the molecules, and that the atoms of the molecules exist separately and distinct from one another, or in a nascent state; and this leads to the hypothesis that in a *nascent state alone* hydrogen is electricity; as soon as it becomes *free*, or the atoms recombine to form molecules, it changes its condition from current to that of resistant. This is indicated in the voltaic cell, wherein, as soon as the positive pole "element" becomes surcharged with the nascent hydrogen, its condition changes and it is found upon the surface of the element as free hydrogen or as resistant too great for the nascent hydrogen or current being evolved within the cell to overcome, then a reverse current begins within the cell, carrying with it particles of the "solution." This phenomenon is called polarization; it can only take place while the positive pole "element" is surcharged with free hydrogen.

If, then, the lightning flash, with its electrical phenomena is hydrogen, and the aurora, with its electrical manifestation, give the same answer to the spectrum's analysis that hydrogen does, can we not say that these things, though called by different names, but having the same characteristics, and attended by the same phenomena, are one and the same thing, and that that thing is hydrogen?

Having thus given a few corroborative facts in proof of the hypothesis, I proceed to attempt defining the laws which govern the generation and action of an electric current, and I shall endeavor to conform the present nomenclature to represent what I conceive to be the true laws.

Strength of current or quantity of current, produced in the voltaic cell is proportional to the volume of hydrogen in the positive element, or to the amount of zinc consumed.

Intensity of current or electromotive force, is proportional to the chemical action in the decomposition of the positive element; the more excessive the action the more intense the current.

Potential, should express the condition which a point or body has in relation to the volume of nascent hydrogen it may possess in excess or defect to that possessed by another point or body. Potential is proportional to the volume of nascent hydrogen, the larger the volume the higher the potential.

Difference of potential, is a difference of chemical condition between two points or bodies, in respect (1) to the volume of hydrogen possessed by them, and (2) to the volume of elements in the one having affinity for elements in the other; and, according to the laws of chemical affinity, there is a constant effort of the hydrogen in the one point or body to seek the elements in the other for which it has affinity, hence this difference of potential ever varies.

Resistance of a body is directly proportional to the volume of hydrogen it contains.

Conductivity, the reverse of resistance, is inversely proportional to the volume of hydrogen a body contains, and directly proportional to the elements having affinity for hydrogen in the body or matter.

PHILADELPHIA, Pa.

ELECTRIC STREET CARS.[1]

BY T. C. MARTIN.

THE great question agitating street railway companies in this country at the present time is the use of some motive agency more economical and convenient than horses. It is no exaggeration to say that after about half a century of patient trial they have become profoundly dissatisfied with animal power and are ready to adopt any system that can establish its claim to their preference. Evidence of their feeling on the subject is seen in the fact that at the last convention of street railway men, the progress of electric motors was reported upon by a special committee whose optimistic statements were heard with pleasure. One of the most prominent members avowed that he regarded the promise of electricity as a motor with which to supersede horses as very encouraging. Another said: "All honor to those who are giving an hour or a dollar to the development of this important agent." A third thought it the duty of the convention to extend an earnest and cordial greeting to every man who was "trying to replace bad with good." These sentiments should, I think, encourage us, who with enthusiastic pride have seen the rapid increase in efficiency of the electric motor, and who, no matter what may be our predilection for particular systems, assert and know that—as a bottom and basic principle from which to start—electricity is more than equal to all the demands that may be made upon it in the special service of propelling street cars.

The struggle for supremacy in this field of occupation may fairly be said to have narrowed itself down to three competitors—the horse, the cable, and the electric motor. Steam used directly is, it seems to me, viewed with more and more disfavor as the years go by, and has within city limits come to be considered very much in the light of a nuisance. The lowest cost of operation per steam motor per day, in usual service, that I have seen quoted authoritatively is $8.50 to $7. But even if steam were cheap, there are grave objections on the score of noise, smell and dirt. The mere fact that steam locomotives have been in successful use 50 years, but are still denied employment on the streets, tells its own story as to public opinion. To some of us the banishment of steam even from the tracks of elevated roads seems a matter of but a few years. As for gas, soda, and compressed air motors, I am not aware that they offer any points of superiority over steam for the specific purpose under discussion.

Coming to horses, we find that in spite of their universal use and their faithful performance of duty, they inspire a discontent anything but complimentary, yet hardly to be wondered at. The statistics of horse cars are important and interesting, and deserve our attention as covering the sphere within which the electric motor will operate. There are, according to the latest returns available for this year, about 625 street railways of all kinds in the United States and Canada. Taking of these 408 horse roads giving full and trustworthy figures, I find that they run 17,331 cars and employ 85,888 horses. If at the same ratio we took all the horse roads, upward of 500, we should arrive at a result of not far short of 25,000 cars and 120,000 horses, a total that probably comes very near the actuality. Taking the other figures, which I have tested by three sources of information, it appears that all the horse-car lines are maintaining a proportion of at least five horses to each car. But that is inclusive, and making a reasonable allowance for the use of different cars for winter and summer, and for idle cars, as well as for "doubling up" in heavy snows, a result is shown of at least eight to ten horses per car. This is the proportion usually cited, and it is brought out on a special examination of the statistics for this city. Thus, the Broadway and Seventh avenue road has 121 cars and 1,350 horses, or not far short of 12 horses per car. The Central Park, North and East River road, with a total of 161 cars, has 1,223 horses, a broad average of 8 horses per car. The Eighth avenue road, with 112 cars, has 1,155 horses, or 10 per car. The Forty-second street and Grand street line has 50 cars and 485 horses, or 9 per car. The Sixth avenue line has 127 cars and 1,296 horses, or 10 per car. The New York and Harlem with 164 cars has 1,321

1. Read before the American Institute of Electrical Engineers, December 7, 1886.

Digitized by Google

horses, or 9 per car. The Third avenue road, returning a total of 360 cars, has to keep up a force of nearly 2,200 horses. The large number of horses required is also to be learned from the fact, stated by Mr. Augustine W. Wright, that those on the North Chicago line, which is a favorable sample, work daily only two hours and seventeen minutes. Or to put it in another way, the 6,158 street car horses of Boston travel each about 10 miles a day only, or two hours' service.

The costliness of horses may be arrived at in yet other ways by the use of comparative figures. Mr. T. C. Robbins, of Baltimore, a street car expert, gives the average cost of horse car per day at $6.50. I have had the same figures given me for Brooklyn and Philadelphia, while Mr. C. B. Holmes, of the Chicago Cable Railway, who has had great experience with horse service, says that the expense per car-mile by the cable system is 10 to 11 cents, as compared with 20 to 25 cents per mile when employing horses. On a daily run per car of 50 miles, that would be at least $12 per day with horse traction, and half as much for cable. Moreover, there are the great extent of valuable land required for huge stables and the heavy depreciation of stock. Few occupations are more exhausting to horses than street car traction, and the average railroad life of a horse is but from three to five years. In other words, out of 100,000 horses, at least 20,000 every year die or become useless for their work, and drag out the remainder of their existence in other occupations. "How are you getting along with those old horses I sold you," said the street railway president to Mr. Sexton, the undertaker. "Pretty well," was the reply. "I tried 'em first in the mourning coaches, but they were too slow for the ladies. Then I put 'em in the hearses, and I haven't heard any complaints from that quarter."

The cable has already made its way into use on a large number of street railways doing a heavy business, and is, it must frankly be admitted, a vast improvement on old methods. It has enabled those roads to handle a traffic that was utterly beyond their capacity before. It has accelerated speed, has lessened accidents, has given the streets a cleaner look, has, it would seem, cut down expense, and has certainly raised the value of property wherever put in. But I doubt seriously whether in view of the enormous first cost of the cable system and the excessive waste of power, it will make very rapid strides, especially when subjected to the rivalry of electric motors. At the recent street car convention, the new cable roads at Kansas City were presented for favorable notice, and as they were evidently considered good specimens, let us accept the figures. The Metropolitan road will cost $50,000 per mile of single track, and I observe that it is claimed with regard to the Philadelphia system that the track there could now be duplicated at about the same cost. The Kansas City cable company gives some interesting results of a test of its engines and machinery, from which I gather that with a total of 159.7 h. p., no less than 119.06 h. p. was required for the cable machinery, leaving only 40.64 h. p. for cars and passengers. In other words, just 25 per cent. was available for actual traffic. This waste will strike electricians familiar with the high efficiency of dynamos and their transmission of power as extraordinary. But it is confirmed by a statement from Mr. C. B. Holmes, of Chicago, who says that his cable railway required for ordinary operation, engines of 477 h. p.; that it took 389 h. p; to move the cable and machinery, and that 88 h. p., or only 18½ per cent., was used for the propulsion of the cars at nine miles an hour. Mr. W. W. Hanscom, in a careful review of the conditions applying to the cable lines of San Francisco, gives a total daily average percentage on the seven roads of 68 per cent. of power for moving the cable, and 32 per cent for the cars and passengers. Two miles of new double-track in San Francisco, fully equipped, have just cost $400,000.

I do not know that these figures call for comment, as those presented later on in regard to electricity will serve for purposes of comparison. But they may be supplemented by one or two observations. It is evident that there is an objectionable rigidity in the cable system and that it has narrow limits of applicability. A cable road, of whatever kind, needs a very large patronage. Mr. P. A. B. Widener, well known in connection with Philadelphia street railways, said last year: "To maintain a cable road you must have a certain amount of business in order to be self supporting. It costs as much to run the cable for half a dozen cars as for half a hundred. Small roads, or feeders to the main line, are run more cheaply by horses." It will be remembered that great trouble was experienced in Philadelphia in rendering the cable system there operative last year. The assertion is made by those who should know that 12 miles, costing between $40,000 and $50,000 a mile, required $250,000 in repairs and renovation inside the twelve months; but, as the *Ledger* put it philosophically at the time of the breakdowns: "It is claimed that the delays and other annoyances that have been experienced by the company have been slight in comparison with those met with in Chicago when the cable road there was in its infancy." We New Yorkers and Brooklynites are more familiar with the mishaps on the East River Bridge, and from the arguments made here and elsewhere against cable roads we have learned that the cables wear out quickly, besides being ceaselessly noisy and requiring a conduit that must have such a depth as to become an unhealthy drain or sewer.

We reach now, in the due course of our survey, the use of electricity as compared with horses or cables. You will, I believe, bear me out when I say that the confidence of electricians in the ability of electrical means to propel street cars is as strong as it could possibly be, and is, moreover, based on no small amount of work and experience. I might affirm that the general introduction of electric motors is now largely a question of coal bills. I might affirm that it has more and more resolved itself into a question of mechanics; and in both statements I should have your concurrence. I might broadly state that in Europe, where a large number of electric roads exist already, they are paying well and multiplying; and that such roads in this country had, some months ago, carried altogether over a million passengers, or a daily traffic of 3,000 passengers for a full running year, without any recorded injury to a single patron, while several new roads have of late gone into successful operation. But at the risk of covering much ground with which you are familiar I shall venture to give an outline of some of the methods by which electricity is applied to street-car service, as well as some of the data establishing its claim to superiority. I do not know of any point on which a fair comparison need be shirked; I do not know of any difficulty that can balk the infinite variety of our electric art, and as this society has never hitherto had the subject before it, I am encouraged to go a little into detail.

We have, in using electricity for street cars, the option of so many methods that the very flexibility of the application becomes a recommendation. We shall, perhaps, best spend our time in considering three or four of the leading methods, with incidental reference to the peculiarities of individual cases in each. I propose to take the third-rail system, the overhead system, the conduit system and the storage system, and, without any intention of invidious discrimination, to pick out, for the exemplification of each, some of the roads and cars that have been running or can be seen and tested.

Let us begin with the third-rail system. The Daft road at Baltimore, now in its second year, has been so often described that full details here are not necessary, but it furnishes some interesting figures. The cost of electric power there against horse-power at $6.50 per car has been $4 per car per day, with an increase for the year of 83,986 passengers. Mr. T. C. Robbins reported as follows to the

Digitized by Google

street car convention: "It was started on a purely commercial basis, as a purely commercial transaction, and has continued, and is now being extended, simply because it has proved its right to stay by the performance, which leaves little to be desired." The largest item in the expenses at Baltimore is coal at $3.50 a ton. Another third-rail road, the Highland at Detroit, on which there are none of the grades and curves that rendered the Baltimore road expensive as to fuel, is in very successful operation. Like the Baltimore road, it has a wheel for making contact, but, unlike it, has the third rail neatly sunken between planks. It runs out of the city for three miles. The car in use is the same as those on Broadway, this city. Mr. Frank Fisher, whose motor is used, informs me that on a recent Sunday, on a thirteen hour schedule, the road carried 5,500 passengers. The coal consumption was a little over 400 lbs. The coal—screenings—costs $1.25 a ton. The success has been so great as to lead to a development of matured plans for the increase of the service there and on a new local road to be begun in the spring.

You will agree with me, I think, that third-rail systems must be limited to a low electromotive force, and to suburban or rural districts. Even there they have a large opportunity.

Coming to the overhead conductor systems, the Van Depoele roads form an important group. These roads are now in operation at Detroit, Port Huron, Mich., Windsor, Can., Appleton, Wis., Montgomery, Ala., and Scranton, Pa. Mr. Van Depoele suspends his feeding conductor by side poles, or, as at Appleton, has double wires, corresponding to the track, but immediately above it at a height of 18 or 20 feet. The little Windsor road, two miles long, with two cars, started in June, 1885, has paid for itself. I may mention that when I went on it last August, one evening, I visited the generating station. It was deserted and in black darkness. I made the trip and then went back to the station. The darkness was blacker, and there still was no sign of attendance, but the 30 or 40 passengers each turn were none the wiser and none the worse. I don't approve such practice however. The Appleton road, with five cars, is the first in this country run by water power, depending, and with great success, upon a pair of turbines that will develop 100 h. p., and are now driving a 60 h. p. dynamo. The Montgomery road is notable as being a complete city system, including ten miles of track. The Scranton road that started last week has two features of special interest. One is that in a city of about 50,000 or 60,000 inhabitants the use of the overhead conductor is allowed. Another is that the line is operated from the electric light station. The road is 2½ miles long, with 12 grades, mostly over 6 per cent. There are already in use two heavy Pullman cars, running at a speed of from 4 to 15 miles an hour. The current is conveyed by a conductor $\frac{4}{10}$ of an inch in diameter, the rails forming the return. A traveler with rollers and a flexible cable passes the current to the motor, which, it is worthy of notice, stands upon the front platform in sight of the driver. The electric light station is well satisfied with only $9 a day for running the 60 h. p. generator, and it is evident, therefore, that an increase of rolling stock will involve very little increase in cost of power. Here is a hint by which electric light men nearly everywhere might profit.

In the overhead conductor category should be included Mr. Daft's new roads at Los Angeles, Cal., one 3½ miles long and the other 2½ miles. A peculiarity is the placing of the motor in the centre of the car, occupying the room of but two passengers, and leaving both platforms clear.

The overhead bare conductor systems are also restricted to currents of low electromotive force. But they, as well as the third-rail systems, do work it is impossible to perform remuneratively by cable, and which would often be beyond the range of horse or mule power on either philanthropic or business principles. Provided permission is obtainable for running the wires, the overhead conductor system seems cheapest, if not best, for cities up to at least 50,000 population. I believe a double overhead conductor system well built should cost from $1,500 to $2,000 per mile. The single conductor is, of course, much cheaper.

There are in the United States about 40 cities with population above 50,000. In almost every one of these it would be necessary to resort to the electric conduit system, third on our list, unless the storage system be tried, or a combination of the two. At the present time, the outlook for electric railways with conduited mains is very favorable.

The first exemplification of a conduit system in this country was given by the Bentley-Knight Electric Railway Company in 1885, at Cleveland. A working section of their line can now be seen at the Rhode Island Locomotive Works, and as it illustrates in a striking manner the principles involved, I will touch on a few of the leading points, now described for the first time. The conduit is made to resist the heaviest wear and strain of street traffic. The surface opening, or slot, is only $\frac{1}{8}$ of an inch wide, and the total width of metal at the street surface is but 3 inches. The conduit is kept clean by a broom of peculiar shape suspended from the car. This broom is said to have swept out in a single trip the accumulation from 12 hours constant snowing. At convenient points catch-pans with sewer connections receive the sweepings and effect drainage. The two main conductors consist of channel iron connected by expansion joints and lined with a continuous strip of copper of sufficient size to carry the current with but small loss of energy. These conductors are fastened to the side walls of the conduit on insulators of vulcanized wood dipped in white lead. The insulators are strongly set in sockets in the cast-iron supporting yokes. Neither the traffic rails nor the conduit structure form any part of the electrical circuit. To provide for switching, a movable tongue is pivoted at the point of branching, so as to rest on the top of the conduit and to be readily set to close either of the branch slots and direct the contact plow into the other. A corresponding conductor tongue within the conduit is moved at the same time. The contact plow for making connection consists of a flat frame hung from the car by transverse guides, on which it is free to slide the whole width of the car and extending thence down through the slot of the conduit. It is provided with a swivel joint, so as to adjust itself to all inequalities of road or conduit. This frame carries two flat steel insulated conductor cores, to the lower ends of which are attached by a spring hinge small contact shoes of chilled cast iron that slide along in contact with the two main conductors. At the upper ends are flexible connections leading to the motor. This plow can be inserted or withdrawn through the slot at will, the spring hinge allowing the contact shoes to straighten out into line with the conductor cores when the plow is pulled upward and the shoes strike the insulating lining with which the slot irons are provided. By no accident, therefore, can anything be left behind in the conduit to obstruct succeeding cars. The plow guides are hung on transverse axes, and are held in a vertical position by a spring catch that gives way when the plow meets an irresistible obstruction, and hence the plow is automatically thrown completely out of the conduit without injury, being also immediately replaceable. The contact shoes will stand weeks of wear, and cost next to nothing. The frame of the plow has wearing guards of hardened steel wherever it can touch the edge of the conduit slot, and these are also readily renewed. Two plows are used on each contact for the sake of absolute reliability, and to prevent flashing at the contact. The connection between the wheels and motor consists of a system of gear wheels and connecting rods, the gears being deadened so as to be quite noiseless. The company makes a completely equipped steel-framed truck, with motor, etc., upon which can be placed any car body. These have a wheel base of 6 feet, a standard gauge of 4 feet 8½ inches, and can be used on curves with a radius of 45 feet. A motor of the Gramme type is used under the car. For long

Digitized by Google

distances the motors are in series, with current constant; for short distances, the motors are put in multiple arc, and a new form of resistance is used.

Such are the main features of the system. Of its eminent practicability there should be no doubt. The question again is one of expense, and I therefore give transcripts furnished me by Mr. R. W. Blackwell, of actual estimates submitted quite recently and now under consideration. The first is for the equipment of existing street railways in the city of New York, 3 miles, 1,440 feet, double track, minimum headway 1½ minutes, average speed 7 miles per hour, running 24 hours per day, very heavy traffic, maximum grade 3 in 100.

CONSTRUCTION AND EQUIPMENT.

Conduit and conductors, 34,560 feet, at $3, $103,680; motor trucks, 37 at $1,200, $44,400; 50 h. p. dynamos, 12 at $2,500, $30,000; steam power plant complete, $27,750; foundation, $5,000; engineering, $3,000—$213,830.

ANNUAL EXPENSE.

Coal, 14 tons per day, at $3, $15,330; engineer and assistant, at $2.50 and $2 per day, $1,642.50; firemen, 3 at $1.50 per day, $1,642.50; machinists, 2 at $2 per day, $1,460; total running expenses, $20,075. To which should be added interest on construction cost ($213,830) at 6 per cent., $12,829.80; and also depreciation of plant at 3 per cent., $6,414.90; total expense and charges, $39,319.70.

The second is for a down-town cross-town road in the city of New York, greatest grade 1 in 12, double track: 12,660 feet conduit (extra heavy), at $4, $50,640; 20 motor trucks complete, at $1,200, $24,000; six 50 h. p. dynamos, at $2,500, $15,000; steam plant complete, $20,000; foundation, $2,000; engineering, $2,500—$114,140.

Of course, I do not present these figures as those upon which all authorities are agreed, but they have their value as being bids on actual work.

The conduit system of Mr. W. M. Schlesinger, in use for four months past by the Union Electric Company at Philadelphia, with a car running 9¼ miles an hour, has noticeable peculiarities. It consists practically of two conduits, the upper of heavy channel iron for connection, the lower of wood or cement for drainage. To insulate the conductors, an angle iron is riveted to the top flange of the channel iron in such a manner that one of its flanges, pointing downward parallel to the main side of the channel iron, forms one side of the slot. In the inverted trough thus formed, the copper bar conductors are fastened, the contact being on the under side. Against the conductors, pulling upward, rub or press springs, making a firm, close contact under control by means of a frame holding the springs. In Mr. Schlesinger's system, the motor is under the car between the axles, and geared to them by means of chains. The motors are intended to work in multiple arc.

There are other conduit systems, among which I might mention the Van Depoele used at Toronto, I believe, in 1884, at the exposition. But my object is not so much to describe all the systems as to bring up main features and relative costs. I will, therefore, pass on to point out that whereas in the cable system, with its costly conduits, the available power for the cars and passengers reaches only about 25 per cent., in the electric conduit system, requiring for generators, conduit and conductors, etc., but half the outlay necessary on a cable system, the net return of power, as you are well aware, reaches at the minimum from 50 to 60 per cent. Mr. G. W. Mansfield, who has had considerable experience with the Daft company, puts it as being at least 56 per cent. I note, too, that with the use of the Holroyd Smith conduit system, the Blackpool road, England, has reported earnings of $1,735 in a week, with a total expense account of $225, running 2,760 miles, and carrying 44,306 passengers.

A distinguishing feature of the conduit system is that it is the only one with which high potentials can be employed on the streets. With it, also the power stations can be placed near ample water supply or where rents are low, or can each be given a section of road to operate.

I approach the next and last system on our list, that of storage, with some degree of nervousness. In more than one quarter the man who comes out with a kind word for the secondary battery is set down as either a knave or a fool. I cannot see why he should be regarded as either, although he may perhaps be more than ordinarily sanguine and hopeful. I have myself ridden very comfortably in a street car propelled by storage batteries, so that I know the thing can be done, and I understand that storage is to be extensively used at an early date by the North Metropolitan Tramway Company in London. At Antwerp, in 1885, after six months' competition with four other cars using either steam or compressed air, the Julien electric storage car took the first prize, awarded by a jury of well-known experts. There were in all twenty-three points of comparison. The Julien car has since been tried in Hamburg, and another has been in operation on the Eighth avenue line in this city. Mr. Widener, of the Philadelphia cable line, has traveled on it and is to try it, being very favorably impressed. But, as he remarked publicly, "The question is as to the cost of maintenance of the cars and the furnishing of motive power." It will be admitted that there are advantages in having each car an independent unit, offsetting the disadvantage of carrying the dead weight of batteries; and that single cars on any road can be taken in hand for change, so that existing rolling stock can be progressively adapted to the new conditions. This involves a smaller initial outlay and gives opportunity to train the present force in its unfamiliar though simple duties. Now, regarding first cost—I have never seen any figures as to the expense of an equipment of a car with storage batteries. It has been said that two sets for an ordinary street car would cost about $1,500. That seems high. The Julien company states that the cost of the horses for a car more than covers the initial outlay of the change, and I believe the firm estimate is also made by the company of a total daily running expense of not to exceed $5 per car in cities on heavy traffic. As to life of the batteries, those in the Hamburg-Julien car have now been in daily use since April, and they show by test a return of more than 80 per cent. of the power with which they are charged. The car is running on regular daily service. In respect to American storage batteries, it may be mentioned that the Electrical Accumulator Company, whose officers have a standing in electrical circles, guarantees two years' life for its new battery and an 80 per cent. return of power. The criticism has been made that ordinarily 20 per cent. of the stored energy is retained on each emission, but obviously that is no loss, forming simply 20 per cent. of the succeeding charge.

Putting it broadly, the storage system, in spite of its various conversions of energy, has a superiority of at least 25 per cent. over cables. Some of you will put it far higher, but as I have said, in the absence of the data of prolonged work, I prefer to put it low.

I think we shall see a number of efforts shortly made in the direction of using secondary batteries for regular work on street cars, and the results will merit our most careful study. There are, moreover, some ingenious propositions for combining the conduit and storage systems, so as to enjoy the benefits of both. Mr. J. M. Pendleton has described a plan of his of this nature, and Mr. Elias Ries, of Baltimore, has also carefully elaborated such a system, in which storage plays an important part.

Here, then, illustrated in a variety of ways and by numerous examples, we have a comparison of electricity with other power for propelling street cars, and an idea is given, very imperfectly, of the wide range of choice that electricity itself offers as to methods and means. Much of what has been said has its direct and favorable bearing

Digitized by Google

on elevated railway traction, as well as on that for underground railways, but the time will not permit me to pursue the subject any further. Many points of discussion arise as to the connection of the car axles with the motor; the use of independent motor cars or of motors on the passenger cars; the types of motors and of conduits or conductors; the potential that is safe under certain conditions; the methods of regulating motor speed; the use of resistances; but all these and others I may leave to you, many of whom are doing practical and creditable work in this field, and who by thus "hitching your wagon to a star," have shown that street cars, if run by electricity, may yet be brought up to the most advanced notions of humanity, comfort, convenience and economy.

All that remains is to press onward and occupy the pre-empted territory that awaits us. As Emerson says: "Our duty is plainly not to throw ourselves across the track, not to block improvement, not to sit still till we are stone; but to watch the uprise of successive mornings and to conspire with the new works of new days." This sentiment may surely be appropriated by modern electricians, who every year put their skill to some severer test, and every year win fresh triumphs. In beginning this street railway work, we may count on a large and profitable travel for some time to come, through the mere novelty of the thing, but as the art improves it will more and more manifest its right to street railway propulsion on the strictest business principles, as well as on every other ground of merit.

DYNAMO-ELECTRIC MACHINERY.[1]

BY J. HOPKINSON, M. A., D. SC., F. R. S., AND E. H. HOPKINSON, M. A., D. SC.

Theoretical Construction of Characteristic Curve.

OMITTING the inductive effects of the current in the armature itself, all the properties of a dynamo machine are most conveniently deduced from a statement of the relation between the magnetic field and the magnetizing force required to produce that field, or, which comes to the same thing, but more frequently used in practice, the relation between the electromotive force of the machine at a stated speed and the current around the magnets. This relation given, it is easy to deduce what the result will be in all employments of the machine whether as a motor or to produce a current through resistance, through an electric arc, or in charging accumulators; also the result of varying the winding of the machine whether in the armature or magnets. The proper independent variable to choose for discussing the effect of a dynamo machine is the current around the magnets, and the primary relation it is necessary to know concerning the machine is the relation of the electromotive force of the armature to the magnet current. This primary relation may be expressed by a curve (Hopkinson, Mechan. Engin. Instit. Proc., 1879, pp. 246 *et seq.*, 1880, p. 266), now called the characteristic of the machine, and all consequences deduced therefrom graphically; or it may be expressed by stating the E. M. F. as an empirical function of the magnetizing current. Many such empirical formulæ have been proposed; as an instance we may mention that known as Froehlich's, according to whom, if c be the current in the magnets, E the resulting E. M. F., $E = \frac{a c}{1 + b e}$. For some machines this formula is said to express observed results fairly accurately, but in our experience it does not sufficiently approximate to a straight line in the part of the curve near the origin. The character of the error in Froehlich's formula is apparent by reference to sheet I. (plate 16), which gives a series of observations on a dynamo machine, and for comparison therewith a hyperbola, F, drawn as favorably as possible to accord with the observations.[2] Such empirical formulæ possess no advantage over the graphical method aided by algebraic processes, and tend to mask much that is of importance.

One purpose of the present investigation is to give an approximately complete construction of the characteristic curve of a dynamo of given form from the ordinary laws of electro-magnetism and the known properties of iron, and to compare the result of such construction with the actual characteristic of the machine. The laws of electro-magnetism needed are simply (Thomson, papers on "Electrostatics and Magnetism;" Maxwell, "Electricity and Magnetism," vol. 2, pp. 24, 26, and 143), (1) that the line integral of magnetic force around any closed curve, whether in iron, in air, or in both, is equal to $4 \pi n c$ where c is the current passing through the closed curve, and n is the number of times it passes through; (2) the solenoidal condition for magnetic induction, that is, if the lines of force or of induction be supposed drawn, then the induction through any tube of induction is the same for every section. Regarding the iron itself, we require to know from experiments on the material in any shape the relation between a, the induction, and α, the magnetic force at any point; for convenience write $a = f^{-1}(\alpha)$, or $\alpha = f(a)$. From these premises, without any further assumption, it is easy to see that a sufficiently powerful and laborious analysis would be capable of deducing the characteristic of any dynamo to any desired degree of accuracy. This we do not attempt, as even, if successful, the analysis would not be likely to throw any useful light on the practical problem. We shall calculate the characteristic, first making certain assumptions to simplify matters. We shall next point out the nature of the errors introduced by these assumptions, and make certain small corrections in the method to account for these sources of error, merely proving that the amount of these corrections is probable or deducing it from a separate experiment, and again compare the theoretical and the actual characteristic.

First Approximation.

Assume that by some miracle the tubes of magnetic induction are entirely confined to the iron excepting that they pass directly across from the bored faces of the pole pieces to the cylindrical face of the armature core. This, we shall find, introduces minor sources of error, affecting different parts of the characteristic curve to a material extent. Let I be the total induction through the armature, A_1 the area of section of the iron of the armature, l_1 the mean length of lines of force in the armature; A_2 the area of each of the two spaces between core of armature and the pole pieces of the magnets, l_2 the distance between the core and the pole-piece; A_3 the area of core of magnet, l_3 the total length of the magnets. All the tubes of induction which pass through the armature pass through the space, A_2, and the magnet cores, and by our assumption there are no others. We now assume further that these tubes are uniformly distributed over these areas. The induction per square centimetre is then $\frac{I}{A_1}$ in the armature core, $\frac{I}{A_2}$ in the non-magnetic spaces, $\frac{I}{A}$ in the magnet cores; the corresponding magnetic forces per centimetre

1. From the Philosophical Transactions of the Royal Society.

2. Added August 17th.—That Froehlich's formula cannot be a thoroughly satisfactory expression of the characteristic of a dynamo machine is evident from the consideration that E should simply change its sign with c, that is, be an odd function of c. There should be a point of inflexion in the characteristic curve at the origin. Another empirical formula $\frac{E}{a} = \tan.^{-1} \frac{c}{b}$ is free from this objection, but still fails to fully represent the approximation of the curve to a straight line on either side of the origin, and it is equally uninstructive with any other purely empirical formula.

Digitized by Google

linear must be $f\left(\frac{I}{A_1}\right)$, $\frac{I}{A_2}$, $f\left(\frac{I}{A_3}\right)$. The line integral of magnetic force round a closed curve must be

$$l_1 f\left(\frac{I}{A_1}\right) + 2 l_2 \frac{I}{A_2} + l_3 f\left(\frac{I}{A_3}\right).$$

In this approximation we neglect the force required to magnetize pole-pieces and other parts not within the magnet coils to avoid complication. The equation of the characteristic curve is then

$$4 \pi n c = l_1 f\left(\frac{I}{A_1}\right) + 2 l_2 \frac{I}{A_2} + l_3 f\left(\frac{I}{A_3}\right).$$

This curve is, of course, readily constructed graphically from the magnetic property of the material expressed by the curve $\alpha = f(a)$. In sheet I. curve A represents $x = l_1 f\left(\frac{\nu}{A_1}\right)$ the straight line B $x = 2 l_2 \frac{y}{A_2}$, curve C $x = l_3 f\left(\frac{y}{A_3}\right)$, and curve D the calculated characteristic.

When we compare this with an actual characteristic, E, we shall see that, broadly speaking, it deviates from truth in two respects: (1) it does not rise sufficiently rapidly at first; (2) it attains a higher maximum than is actually realized. Let us examine these errors in detail.

1. The angle the characteristic makes with the axis of abscissæ near the origin is mainly determined by the line B. We have, in fact, a very considerable extension of the

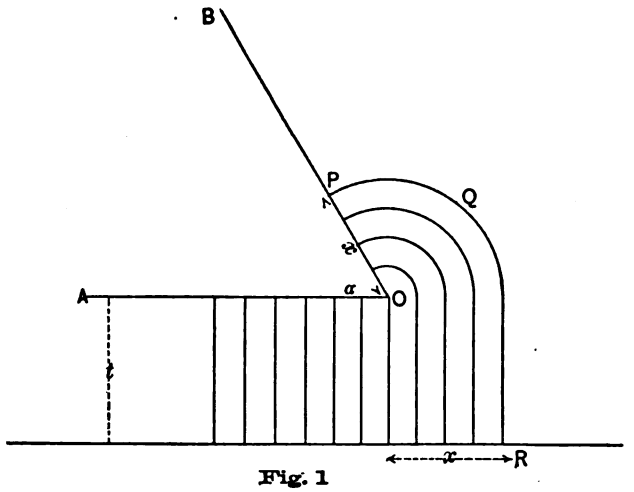

Fig. 1

area of the field beyond that which lies under the bored face of the pole-piece. The following consideration will show that the extension may be considerable. Imagine an infinite plane slab, and parallel with it a second slab cut off by a second plane making an angle, α. We want a rough idea of the extension of the area between the plates by the spreading of the lines of induction beyond the boundary. We know that the actual extension of the area will be greater than we shall calculate it to be if we prescribe an arbitrary distribution of lines of force other than that which is consistent with Laplace's equation.

Assume, then, the lines of force to be segments of circles centre O, and straight lines perpendicular to O A. The induction along a line, P Q R, will be $\frac{v}{(\pi-\alpha)x+t}$, v being difference of potential between the planes, and the added induction from O P B will be

$$\int_0^x \frac{v\,dx}{(\pi-\alpha)x+t} = \frac{v}{\pi-\alpha} \log. \frac{(\pi-\alpha)x+t}{t}.$$

Thus if $\alpha = \frac{\pi}{2}$ we have for $x = t$, $2t$, &c.

x ..... $\frac{1}{\pi-\alpha}$ log. $\frac{(\pi-\alpha)x+t}{t}$
t ..... .599
$2t$ ..... .904
$3t$ 1.109
$4t$ 1.263
$5t$ 1.387
$10t$ 1.792

showing that the extension of the area of the field is likely to be considerable.

2. The failure of the actual curve to reach the maximum indicated by approximate theory is because the theory assumes that all tubes of induction passing through the magnets pass also through the armature. Familiar observations round the pole pieces of the magnets show that this is not the case. If ν be the ratio of the total induction through the magnets to the induction in the armature we must in our expression for the line integral of magnetizing force, replace the term $f\left(\frac{I}{A_2}\right)$ by $f\left(\frac{\nu I}{A_2}\right)$; ν is not strictly a constant, as we shall see later; it is somewhat increased as I increases owing to magnetization of the core of the armature, and it is also affected by the current in the armature. For our present purpose we treat it as constant.

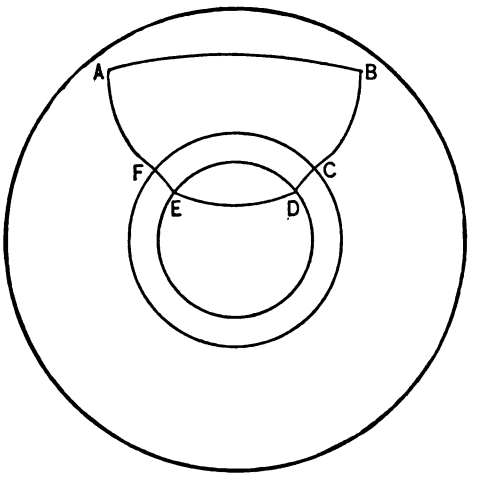
There is yet another source of error which it is necessary to examine. Some part of the induction in the armature may pass through the shaft instead of through the iron plates. An idea of the amount of this disturbance may be readily obtained. Consider the closed curve A B C D E F, A B and F E D C are drawn along lines of force, A F and B C are orthogonal to lines of force. Since this closed curve has no currents passing through it, the line integral of force around it is nil; therefore, neglecting force along E D, we have force along A B is equal to force along F E and D C. In the machine presently described we may safely neglect the induction through the shaft; the error is comparable with the uncertainty as to the value of l_1; but in another machine, with magnets of much greater section, the effect of the shaft would become very sensible when the core is practically saturated.

The amended formula now becomes

$$4 \pi n c = l_1 f\left(\frac{I}{A_1}\right) + 2 l_2 \frac{I}{A_2} + l_3 f\left(\frac{\nu I}{A_3}\right) + l_4 f\left(\frac{\nu I}{A_4}\right) + 2 l_5 f\left(\frac{I}{A_5}\right)$$

where l_4 is the mean length of lines of force in the wrought

Fig. 2



iron yoke, A_4 the area of the yoke, l_5 and A_5 corresponding quantities for the pole pieces, the last two terms being

Digitized by Google

introduced for the forces required to magnetize the yoke and the two pole pieces.

We now repeat the graphical method of construction exactly as before, the actual observations of induction in armature and current being plotted on the same diagram. Sheet II. (plate 17), in which curve, G, represents the force required to magnetize the yoke, and curve, H, that required to magnetize the pole pieces. Before discussing these curves further, and comparing the results with those of actual observation, it may be convenient to describe the machine upon which the experiments have been made, confining the description strictly to so much as is pertinent to our present enquiry.

(*To be continued.*)

ABSTRACTS AND EXTRACTS.

THE ELECTRICAL TRANSMISSION OF ENERGY.

WHILST M. Marcel Deprez has been occupied in carrying out his important series of experiments on the electrical transmission of power between Creil and Paris, of which we have from time to time published particulars, M. Fontaine, who, at the Vienna exhibition of 1873, made the first public demonstration of this nature, addressed himself to the task of realizing in a simple and inexpensive manner, a means of electricial transmission which should fulfill the conditions of the imposing programme prepared by his scientific competitors. He first cut out one of the costly elements of the installation by placing the generating and receiving dynamos in the same building, and by substituting for the line connecting the station at Creil with that at La Chapelle, a resistance equal to 100 ohms. Of course the objection may be fairly made that an experiment which is to serve as the basis of practical applications, must be carried out as closely as possible under actual conditions, with a working line, which would introduce all the difficulties and contingencies of practice. But on the other hand this strict approximation to reality is purchased very dearly, and the information it affords is scarcely worth the cost of 112 kilometres of heavy cable, and special posts required for the Creil experiments. When it is possible to obtain at a nominal cost the equivalent of this line, with the additional advantage of being able to follow each phase of the experiment at both ends at the same time, without any of the complications inseparable from widely separated stations, there can be little question as to the advantage of M. Fontaine's method.

The experiments were carried out at the works of the Compagnie Electrique, and no new apparatus was introduced during the trials. The dynamos employed were Gramme machines of the "Superieur" type, but in order to attain the enormous tensions employed by M. Deprez with his especially constructed dynamo, M. Fontaine placed four machines in series in such a way as to obtain a fall of potential of 6,000 volts; the current was about 10 amperes. The receiving machines were three in number, of similar type, and also arranged in series, and the primary motor was a 100 h. p. engine. Under these conditions an experiment was carried out by M. Mascart, with the following results, which were embodied in a paper submitted by him to the Academy of Sciences on the 20th of October last:

Speed of engine	56 rev. per min.
" " generators	1,298 " " "
Difference of potential at the terminals of first dynamo	1,490 volts.
Difference of potential at the terminals of second dynamo	1,505 "
Difference of potential at the terminals of third dynamo	1,498 "
Difference of potential at the terminals of fourth dynamo	1,508 "
Difference of potential at the end of conductor	5,996 "
Resistance of line	100 ohms.
Current	9.34 amperes.
Power of engine	112.8 h. p.
Useful energy of engine	85 per cent.
Energy imparted to generating dynamos and transmitted to receivers	95.88 h. p.
Speed of receiving dynamo	1,120 revolutions.
Work delivered at the brake	49.98 h. p.
Efficiency	52 per cent.

If these results are compared with those embodied in the report of M. Maurice Levy upon the Creil experiments, it will be seen that the two experiments have been made under technical conditions practically similar. But the former are far superior as regards the economic phase of the problem, M. Levy estimates that the transmission of 50 h. p. from Creil to Paris would require a generating dynamo costing 50,000 francs and a receiver costing 30,000 francs, besides the conductor. In the experiment of the Compagnie Electrique, the seven Gramme machines represented a total value of 16,450 francs and a total weight of 8,400 kilos, so that the transmission of 50 h. p. through a resistance of 100 ohms involved, per horse-power, the use of 167 kilos. of dynamo at a price of two francs per kilo.

These figures are interesting because they correspond with those under the best industrial conditions that have been realized up to the present time in the transmission of power through considerable distances. Moreover, it is evident that there would be a great advantage in using a uniform and commercial type of dynamo grouped to any desired extent, instead of building special machines for every separate nature of installation. Whatever may be their practical value, it is clear that these experiments of M. Fontaine mark a distinct progress towards the solution of the interesting problem of the transmission of power by electricity.—*Engineering.*

NEW METHOD FOR DETERMINING THE TIME OF OSCILLATION OF A MAGNET.

IN a recent number of the *Annalen der Physik und Chemie*, H. G. Hausemann describes a new arrangement for determining the periodic time of a suspended magnet. This method, which can be adopted for any similar purpose, consists of an ingenious application of photography for recording the differences of agreement in position between the magnet under observation, and a seconds pendulum. The magnet is provided with a mirror in the ordinary way, by reflection from which the divisions of a scale mounted before it can be read off in a telescope. A small mirror fixed to the pendulum and parallel with its plane of oscillation, reflects, when at rest, the beam of an electric light upon a prism, provided with a broad slit crossed by a narrow vertical bar; from the prism the light is reflected upon the mirror of the magnet, from which, when near its neutral position, the barred slit is focused in a small photographic camera especially constructed for the purpose. The slide of the latter is furnished with a micrometer screw, so that the plate can be moved through a known distance between any two exposures. The elongations can be read on the telescope in the usual way, and by measurement of the distance between the images on the negative, the number of oscillations of the magnet corresponding to a given number of those of the pendulum can be accurately determined, if the times of exposure are chosen when the pendulum and magnet are both near their positions of rest. This method naturally admits of extreme accuracy in the determination of the quantities sought for besides reducing the time required.

COFFERDAM.

THE name of "cofferdam" has been given to a curious substance, a preparation of cellulose, which has recently been obtained by a young French chemist, M. P. Germain. Its uses in connection with electricity have been investigated by M. André Reynier, the electrician to the Société

Digitized by Google

Genérale des Téléphones. From a report which has been written by M. Reynier for *L'Electricien* we gather that "cofferdam" or "sporique," as its finer variety is termed, is prepared from the husks of the cocoa-nut; it has the color and aspect of cocoa powder. The extraordinary properties of this substance arise from its extreme lightness, its specific gravity being represented by the abnormally low figure of 0.08. Under the simple pressure of the hand its volume can easily be reduced to one-third, and even then its density is only about one-fourth that of good sponge. Its absorbing power surpasses that of all other known material. A given volume of "cofferdam" can easily be made to take up a volume of liquid equal to itself, without any perceptible increase in the total volume; or, in other words, the volume occupied by the cofferdam in the combination is negligible. A good sponge will absorb seven times its weight of water, cofferdam absorbs 12.5 times its weight of water. The substance has hitherto been found to be insoluble both in acids and in alkalies and in solutions of salts. It is, therefore, evident that it will thus readily lend itself for use in primary or secondary batteries. M. Reynier states that the resistance of a battery is not perceptibly increased by its presence, and it is suggested that by saturating two separate slabs of the substance it may be employed in two fluid batteries, thus doing away with the porous cell. Not only are the liquids thus kept separated and preserved from accidental spilling, but it is also found that the loss from evaporation proceeds much more slowly. It would appear that the substance is certainly worth a trial for the purpose indicated. —*Electrician* (London).

SELF-INDUCTION IN VOLTMETER COILS.

In reply to a correspondent, M. Hospitalier gives the following experiment, to illustrate the effects of self-induction in the coils of a voltameter. Place in circuit an incandescent lamp, an electro-dynamometer, a resistance without self-induction, and an alternating current machine, and connect the voltmeter in parallel with the lamp. By adjusting the speed of the machine and the value of the resistance, bring the lamp to its normal luminosity; note the readings of the dynamometer and the voltmeter. Now increase the speed of the machine, and by adjusting the resistance again reduce the lamp to normal incandescence. The dynamometer reading will be the same as before, but the voltmeter reading will be smaller. The greater the increase in velocity, the greater will be the difference between the two readings of the voltmeter. Are we to imagine that the number of watts consumed in the lamp is different in the two cases? Certainly not. We are simply to conclude that a voltmeter containing a coil inductively-wound, especially if there be also a soft iron core, is utterly useless for measuring alternating currents.

A SERMON TO EMPLOYES.

The following is a verbatim copy of a notice which the Chicago, Burlington, and Quincy Co. has had printed, framed, and sent to various shops and offices. They are posted for the benefit of the employés. The sentiment conveyed is given as that which actuates the officials of the company in their treatment of employés. "The servant, man or woman, who begins an application for service by inquiring what privileges are attached to the offered situation, and whose energy is shown chiefly in stipulations, reservations, and conditions to lessen the burden of the place, will not be often worth the hiring. The clerk whose last place, was 'too hard for him' has a poor introduction to a new sphere of duty. There is only one spirit that achieves a great success. The man who seeks only how to make himself most useful, whose aim is to render himself indispensable to his employer, whose whole being is animated with the purpose to fill the largest possible place in the walk assigned to him, has in the exhibition of that spirit the guarantee of success. He commands the situation, and shall walk in the light of prosperity all his days. On the other hand, the man who accepts the unwholesome advice of the demagogue and seeks only how little he may do, and how easy he may render his place and not lose his employment altogether, is unfit for service; as soon as there is a supernumerary on the list he becomes disengaged as least valuable to his employer. The man who is afraid of doing too much is near of kin to him who seeks to do nothing, and was begot in the same family; they are neither of them in the remotest degree a relation to the man whose willingness to do everything possible to his touch places him at the head of the active list."

MAGNETIC FIELDS.

Under the above heading, I observe in your issue of November 12th that Messrs. Mather and Platt claim priority for an application of short, thick electro-magnets in 1883, to the use of a form of electro-magnet for dynamo machines, which a knowledge of the laws of electro-magnetism would appear to point out in many cases as the most suitable and efficient—they would appear to claim priority in the use of short and thick electro-magnets more especially in connection with a Siemens or Edison armature, and they also assert thereby to have "led to entire reconstruction in this respect of all modern types of dynamo machines."

As regards types with armatures not of the Siemens, I should like to point to the short and massive magnets used in the Brush machine, and which have survived, as recently seen in the colossal Brush electro-metallurgical dynamo, to successfully compete with the reconstructed dynamos.

The Bürgin in 1879 also appeared to have had massive field magnets, as also the Heinrichs in 1880.

Of armatures of the Siemens type, the well-known Thomson-Houston appeared in 1880, the armature revolving, it is said, in an intense field; the magnets certainly do not appear to have contained much metal, but the field coils are extremely short and of large diameter.

Lastly, the Weston dynamo machine with Siemens armature, and which was originally built with multiple magnets, as in Edison's machine, appeared in 1882, with double horse-shoe, short and massive magnets, and to which machine with one of its magnets removed, the Edison-Hopkinson of to-day is extremely similar; from the engravings appearing in *Engineering*, in 1882, the Weston field magnets appear in length about twice the diameter of the armature, and the aggregate sectional area of the double field appears to be much greater than the cross-section of the armature; high character of design is evident from the fact of the perfect self-regulation, though only shunt wound.

No doubt there are other instances of well-proportioned magnets, but this is sufficient to show that the successful results accruing therefrom in dynamo machines were well known before 1883.—G. E. D. in *Electrical Review* (London).

HORN'S ELECTRICAL TACHOMETER.

The electrical tachometer of Dr. Horn, of Leipzig, is based upon Arago's well-known observation, that a magnetic needle suspended over a rotating copper disc, is deflected in the sense of the rotation. To render the device practical, Mr. Horn replaces the weak earth magnetism by the field of a strong steel magnet of the ordinary horse-shoe type, the needle by an I-shaped armature of soft iron, and the copper disc by a strong copper capsule. The armature needle moves in the plane of the magnet inside the rotating capsule. As the

Digitized by Google

foucault currents induced are proportional to the intensity of the field and to the velocity of rotation, and as the magnetic moments with which the needle is drawn back to its normal position at least between the limits of zero and 45 degrees, are also proportional to the angles of deflection, the deflections will be proportional to the speed. The gauging of the instruments is done experimentally. In the smaller instrument the needle is two inches long, and the diameter of the copper capsule a little greater. The axis of the revolving capsule may be fitted with a three-cornered top to fit into a corresponding cavity in the revolving shaft. Experiments on a minor scale have convinced Mr. Horn that small variations in the intensity of the magnetic field will not influence the deflections of the needle.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Conduit Work Postponed on Account of the Weather.—Electric Railways and Motors.—The Baltimore and Ohio to Change its Quarters.—A Little Telephone War at East Orange, N. J.—Hackensack Wants Electric Lights.—The Electric Accumulator Company.

THE early arrival of an "old fashioned" winter put a sudden quietus on the extension of electrical conduits in this city, much to the satisfaction of some parties who were expected to do a large quantity of work in a short space of time, for which they were not thoroughly prepared. Winter is the proper time, however to fell trees, and it is the fond hope of the subway commissioners, that Sixth avenue may be the scene of a chopping bee next month, and that the work of clearing away the poles will be duly chronicled in the daily papers. A considerable amount of cable has already been drawn into the Broadway conduit of the Western Union company, which, together with contemplated cables on the elevated railway structures will make a fair beginning so far as that corporation is concerned. The question of burying the arc-lighting wires is still unsettled however, and no definite plans have been agreed upon. Whether the existing air lines will last until a conduit is prepared for them is a very doubtful question.

The use of electricity on street railways is not receiving much encouragement in this city. The traffic of all descriptions is becoming so immense that the only relief appears to be from underground lines, or more elevated roads. A plan for a cross-town road between Washington and Fulton markets has been at least temporarily defeated by a veto from the mayor. All of the electrical engineers interested in electric railroading are busily engaged, some in practical work, and some experimenting with a fair prospect of making decided progress during the coming year. It is a most important branch of the business, and when we realize that steam locomotion has apparently reached its limit of speed, it is apparent that there is still room for progress.

In the line of small motors, it may be noted that there is a rapidly increasing development, and their practical use in New York city will not be a novelty two years hence.

The Baltimore and Ohio Telegraph Co., will soon begin preparations for a radical change in the location of its headquarters. The old Brandreth House, corner Canal street and Broadway, is to be refitted for the joint occupancy of the Baltimore and Ohio railroad, telegraph, and express offices. While there is a large amount of telegraphing done in that part of the city, it has never before been looked upon as a suitable location of a main office, but it should be borne in mind that branch offices are now a very important factor in the telegraph business, and that wherever various connecting lines converge and messages are relayed, whether at Harlem or the Battery, such a centre of electrical industry will be considered a main office. The expense of making a change of this character is such, that it hardly seems probable that any immediate consolidation with the Western Union company is to be looked for.

Quite a "merry war" lasted for two or three days in Park avenue, East Orange, N. J., over the attempt of the New York and New Jersey Telephone Co. to erect poles and stretch a line of wires along that avenue. A number of the property owners laid their grievance before the township committee, after which Mr. Bingham went home, got out an axe, and chopped down four poles in front of his property, near North Clinton street. Next day Mr. Broome secured an injunction to restrain the company from continuing the work in front of his property, and when its men tried to extend the wires in front of the Dwyer property, near Alington avenue, Mr. S. M. Long, the agent for Mr. Dwyer, threw himself into the breach, and with the help of chief of police Blaurock, effectually resisted the trespass. Mr. Hyde, the telephone people's attorney, at length promised that the work should not be carried on any further until the consent of the property owners should be obtained.

Hackensack, N. J. is now pining for an electric light system, because the brilliancy of the rival town of Passaic may be seen in the distance across the meadows. If their mosquito killing qualifications were only more generally known, arc lights would be still more popular throughout the state.

The business of the Electric Accumulator Co. has advanced far enough to bring on a strike at its Newark factory, where some of the men engaged in treating the lead plates of storage batteries, concluded that the pay they were getting was not quite sufficient to counteract the effects of lead colic. No work, however is so dangerous but that men can be found who are willing to undertake it, and the manufacture of accumulators will continue. The determined manner with which this young company has grappled this electrical conundrum, and the character of the men who are identified with it, leads to the belief that we shall soon hear good reports from what is, comparatively speaking, an unexplored field.

NEW YORK, December 21st, 1886.

PHILADELPHIA.

The Edison Light.—Successful Electric Lighting at Harrisburg and Elsewhere in Pennsylvania.—The Western Union and Bankers and Merchants' Suit.—Long-Distance Telephoning.

A MEETING will be held in a day or two by persons interested in the Edison Electric Light Company of Philadelphia, which was recently granted a charter, to form a temporary organization and to formulate plans for a permanent organization.

Among the prominent business men of this city who are actively interested in the matter, and who are working with W. Preston Hicks, the agent of the Edison company, who has an office at 108 South Fourth street, are Charles M. Swaim, B. K. Jamison, Amos R. Little, Henry M. Dechert, and Samuel B. Huey.

There are many electric light companies in Pennsylvania, each of them paying from 6 to 25 per cent. interest to stockholders. The plant at Harrisburg is one of the best in the state, but there are others almost as good in Reading, Wilkesbarre, Lancaster, West Chester and Chester. The offer of the New York company to establish a plant in this city on the same basis as those in New York and Boston was promptly accepted, and the men named above say they intend to have Philadelphians supplied with better light than ever before. One of the Philadelphians who has taken a very active interest in obtaining the charter said last evening:

"It is a first-class business enterprise, and I have not the least doubt but that it will pay as well, or even better, here than in other cities where it has been tried. Our main object will be to give to Philadelphians the best and cheapest light for their dwellings by night, as well as to furnish cheap motive power for running machinery, etc., by day, and all by the same plant. It is claimed that the light can be provided for much less money than the gas now in use."

The lawyers representing the various interests in the litigation concerning the receivership of the Bankers and Merchants' Telegraph Company came before Judge Butler, in the United States Circuit Court recently, and argued a number of motions in the cause. Colonel Robert C. Ingersoll, who represents the United Telegraph Lines Company, of New York, which is deeply interested in the Bankers and Merchants' Company, asked leave, on behalf of Clinton P. Farrell, the recently appointed receiver of that company in this circuit, to bring suit for damages against the Western Union for the cutting of the Bankers and Merchants' wires. The application was granted. He also asked that the bill of complaint filed on behalf of the Farmer's Loan and Trust Company for foreclosure under the Bankers and Merchants' mortgage be dismissed.

Messrs. Turner & McClure, of the New York law firm of Turner, Lee & McClure, who represent the Trust company, asked that the latter be allowed to intervene as party defendant in the suit of Edwin Middleton against the Bankers and Merchants' company, and also that the appointment of Mr. Farrell, as receiver of the latter, be set aside. It was urged that the gentleman was related by marriage to Colonel Ingersoll, and therefore could not be considered as a disinterested party. Mr. Ingersoll contended that Mr. Farrell was in every way fitted to fill the position, and that the question of relationship ought not to be taken into consideration. The other side then urged that if the court decided to allow Mr. Farrell to remain as receiver, a co-receiver would be desirable to act with him. After an order had been granted making it necessary that the Trust company be notified of all matters that may come up before the court, or the master in the case, the argument closed.

Judge Butler then declined to appoint a co-receiver.

The guests of the Lafayette Hotel amused themselves the other day by chatting with their friends in New York and Brooklyn over the long-distance telephone system, with which the hotel has just been connected. Everybody was anxious to

Digitized by Google

test the new system, and all were pleased with its successful operation. Long-distance telephony will be a permanent attachment of the Lafayette.

PHILADELPHIA, December 17, 1886.

BOSTON.

New Weather Signals.—Western Union Telegraph Co. Sued for Taxes.—A New Telegraph Co.—The Erie Telephone Co. Suits.—Resignation of Vice-President Bowditch.—Break-down of Martha's Vineyard Cable.—Underground Construction by the Edison Light Co. and the N. E. Telephone Co.—Electric Light and Electric Railroad in Boston and Suburbs.—Electric Station Indicator on the Boston & Maine R. R.—Boston's Antiquated Fire-Alarm Bells.—Edison Light Progress in Boston.

THE chief signal officer of the United States signal service has issued a circular descriptive of the new code of weather signals adopted by the signal service for the inland stations, which are to be used on and after March 1, 1887. The indications are to be telegraphed as at present at one o'clock A. M., and are intended to cover the weather for the succeeding twenty-four hours, beginning at seven o'clock A. M. The signals to be used are as follows: No. 1, a white flag, six feet square, which will indicate clear or fair weather, no rain. No. 2, a blue flag, six feet square, will indicate rain or snow. No. 3, a black triangular flag, six feet at the base and six feet in length, will always refer to temperature, and will be used as follows: When placed above No. 1 or No. 2, it will indicate warmer weather; when placed below these flags it will indicate colder weather; when this black signal is not displayed in connection with either of the other signals, the indications are that the temperature will remain stationary, or that the change will not be above 5° from that of the previous twenty-four hours. The cold wave flag is No. 4, a white flag six feet square, with a black square in the centre. This signal will not be displayed unless a temperature of 45° or less is expected, nor is flag No. 3 to be displayed with it.

At the request of the state treasurer, a suit has been brought by the attorney-general against the Western Union Telegraph Company. A bill was filed in the State Supreme Court last April to enjoin the company from doing business in Massachusetts, because it has not paid any taxes for the year 1885. The amount was $10,618, which was due November 2. As it is a foreign corporation, the company removed the suit to the United States Circuit Court, and there filed an answer, admitting substantially all allegations in the bill of complaint, but claiming that the company really owed only a small fraction of the tax, because most of its lines are upon railroads, which are declared post roads by congress, or are over or under navigable waters, which are in the jurisdiction of congress. The first of the hearings in the suit was held before Francis S. Fiske, who has been appointed examiner, on Saturday the 27th ult. The defendant has two defenses. The main one is that by a law of the United States, with the provisions of which the company has complied by running its lines along the national post roads and by giving priority to government business, it is exempted from taxation. For a further defense it is alleged that even if the company is liable to taxation the amount assessed is far in excess of what would justly be due.

The Brockton City District Telegraph Company filed its certificate of incorporation on the 3d inst., in the county clerk's office at New York. It has a capital stock of $15,000, with the privilege of increasing to $25,000. The company is to run its lines of telegraph from Brockton, Mass., through that state and Connecticut, to New York.

After adjournment of over four months, the hearing in the suits brought against the Erie Telephone & Telegraph Company by three of its officers to recover a large amount of money alleged to be due them for services, recommenced Tuesday morning, November 17th, in the court house at Lowell. The direct examination of Charles J. Glidden, till recently treasurer of the Erie company, was resumed by General Butler. A great mass of evidence with regard to the transfer of the southwestern company of Arkansas, to the southwestern company of New York, showed that at a meeting of three directors they accepted their own resignations and appointed their own successors. General Butler claimed that the transfer was illegal, as the deed was not sealed or witnessed.

The Cleveland company purchased for $412,500 capital stock originally $150,000. The capitalization was first $1,000,000. Later it was increased to $1,500,000. The cash profits for seven members of the syndicate were $377,500. The profit of William H. Bent, now suing for services as attorney on the transaction, was $50,000. The capital of the Cleveland, northwestern and southwestern companies was $210,000. This was swelled to $5,000,000, of which $2,000,000 was kept in the treasury. Five millions might have been retained as well as $2,000,000. It is only a matter of form.

A mass of testimony was introduced from day to day; the final upshoot of the matter, was, that on the 2d of December, the suit of William H. Bent against the Erie Telephone Company was decided in favor of the company by the arbitrators. This affair has been a disgraceful exhibit.

Mr. Chas. P. Bowditch has resigned the vice-presidency of the American Bell Telephone Co., and directorship in the same, and also his directorship in the New England Telephone Co. There have been rumors of other resignations of telephone men, the truthfulness of which will soon appear.

The government cable between the islands of Martha's Vineyard and Naushon gave out Thursday, December 2d. The steam collier Wilkesbarre was seen anchored on the line, and it is presumed her anchor fouled and broke it. This is the first interruption in this cable since it was laid, about a year ago.

The Edison Electric Light Co. have been busy the past month putting down their underground cables. A large force of men was engaged in burying electric wires in Washington street. A shallow trench was dug on the easterly side, and in it were laid three iron tubes, each one containing three large copper wires imbedded in asphalt. These are the main conductors for the Edison incandescent electric lighting system. A similar trench will be dug on the westerly side of the street, and six tubes, containing eighteen wires, will be placed in it. Within a few weeks the company will have facilities for supplying twenty thousand electric lamps. The main station is in the rear of Masonic Temple.

The New England Telephone Co. have pushed their underground work steadily down Tremont street, using mainly the wood conduit, mentioned in November letter. At the lower end of Tremont street, at Roxbury station, 2,600 feet of the Richardson carbonized stone cement conduit, is being put in place. This conduit is in four feet lengths of square cross-section, with one end concave and the other convex, to make good end joints—it has nine 2½-inch holes for cables.

The Chelsea aldermen, on the evening of the 16th ult., received from the New England Underground Telephone and Electric Light Company a petition for leave to open streets in Chelsea to lay underground wires, from branches in Salem and Lynn, to the main office in Boston; referred to the street committee.

The Boston Consolidated Street Railway Company has filed a charter in the secretary of state's office, asking the Legislature for authority to construct, maintain, and use railways in Brookline, Cambridge, Somerville, and Chelsea. President Powers says it is not probable that the Consolidated will adopt the cable system this year, though it may do so in 1887. He was of the opinion, however, that the use of an electric system was more probable than that of a cable. The Daft and Sprague motors, and perhaps some others, Mr. Powers said, had shown good results, and upon the whole, were far more likely to be adopted than the cable system or surface roads.

There are three petitions from projectors of elevated roads on file for the next legislature. Thomas J. Mayall, of Reading, desires to build an elevated railway between Jamaica Plain and Boston Common, to be operated by cable, electricity, pneumatic tube or steam; John W. Candler, Roland [redacted]thington, M. D. Ross, and others, ask for incorporation as the Boston Elevated Railroad Company, with power to build, maintain and operate an elevated railroad from some point at Franklin Park to some point at or near Post Office square, Park square or Scollay square, all in the city of Boston; and the people interested in the Moulton system again petition for incorporation as the City Elevated Railroad Company with authority to build and operate a circuit road from Scollay square to Harvard square, Cambridge.

There appears to be a general desire of the gas companies to go into the business of furnishing electric light and power. Petitions with this end in view have been filed by the Boston, the Bay State, the Newton & Watertown, the Brookline, the Clinton (which asks to increase its capital stock to an amount not exceeding $250,000), the Roxbury (which also asks for authority to lease or transfer its franchise, lease its works or contract with others to carry on its works), the Chelsea (to furnish Chelsea and Revere), the South Boston (with authority to acquire by purchase or lease the property of or contract for carrying on the works of any other gas company whose territory adjoins its own), the Jamaica Plain, the Cambridge (supplying Cambridge and a part of Somerville), the Dorchester (with authority to sell and convey its property and franchise), and the Newburyport companies.

A representative of the Boston Gaslight Company states that the use of electric lights in some stores has not decreased the consumption of gas, as other stores have used more gas than formerly in order to make a brilliant illumination. It is not the intention of the company to manufacture water gas unless the price of labor is increased. The representative of the company said gas is likely to come into general use for other purposes besides illumination. For example, it is now used to advantage in gas engines, in which the motive power is gained by a series of regulated explosions. These have not come into use so much in Boston as in some other sections. It is also valuable for heating and cooking. He thinks the future of electricity is more in the line of motive power than of light.

The Salem Electric Light Company has elected officers for the

Digitized by Google

ensuing year as follows: President, C. H. Price; directors, C. H. Price, J. F. Almy, I. P. Harris, George M. Harris, Z. A. Gallup, B. W. Currier, and S. Fred Smith; clerk and treasurer, Henry M. Batchelder. The capital stock of the company is to be increased from $40,000 to $70,000. The company has 250 incandescent lights, 129 city arc lights, and 105 commercial arc lights in use.

At a meeting of the Lynn aldermen on Nov. 16th, a proposition to light the City Hall by the Sawyer & Man system of electricity was referred to the committee on public property. Mayor Russell has executed a contract with the Cambridge Electric Light Co. to furnish the city with lights for one year at the rate of 55 cents per night for each light.

The Electric Light Co. of Salem ordered the fire-alarm wires removed from their poles where there were lights, and as the order was not complied with, and the light company claimed that it was dangerous to the persons operating the lights, the wires were thrown into the street on Dec. 9th.

During the last few weeks the six o'clock P. M. train from Boston on the Eastern division of the Boston & Maine railroad has had in operation a station indicator. In the upper left hand corner of each end of the cars is a cherry box, about eighteen inches square. Gilt letters on a dark glass front say, "The next station is," and then follows a blank space cut in the glass about a foot in length and two inches wide. This remains blank until the train has crossed the Charlestown and Somerville "know-nothings," when a slight whirring noise is heard in the box, followed by the sharp ring of a bell. The word "Chelsea" appears, and the whole reads, "The next station is Chelsea." Inside the box is a cylinder run by clockwork, and the works move by electricity. On the cylinder is a series of wooden slats with the names of stations painted on them in plain letters. Every indicator on the train may be moved by a gentle touch on a push button in any one car or on the locomotive. Those on this train have been operated from the baggage car.

Years ago, New York, Chicago, Brooklyn, and other large cities, abandoned the antiquated system of clanging the bells when there was a fire, but in Boston the alarms have been given on all the bells all over the city for a fire in any part of the city. The question has been frequently asked why the bells in East Boston should be rung for a fire in Dorchester, and why should the people in Charlestown be waked in the middle of the night to hear the bells clang out the warning that an ash barrel in Brighton was ablaze. But no answer has ever been made that would satisfactorily account for this state of things. The present board of fire commissioners has decided, however, to reduce the number of bell alarms to the minimum, and it will not be long before in the city proper, north of Dover street, the system will be abandoned altogether. And the commissioners have decided upon this policy, and, in fact, have begun to put it in operation without any flare of trumpets.

But as long as the fire department of Boston is constituted as it is at present, the system of bell alarms cannot be completely abandoned. In the city proper, or wherever the men are permanently stationed, the bell alarm is of no use to them. When an alarm is given from a box, the firemen in the houses receive it on the tapper, and are on their way to the fire before the gong rings. The men sleep in the houses, and are there at all times except when away at their meals or on a leave of absence of longer or shorter duration. But in the outlying districts, such as Dorchester, Roxbury or East Boston, there are "call" companies and "call" men, who have other employment besides fire duty, and who do not sleep in the houses of the department. They depend upon the bells to notify them of the fire.

Four years ago the system of incandescent interior lighting was introduced in Boston by Mr. Edison. It was applied before and behind the scenes in the new Bijou theatre, and for a time was a novelty. The use of the new light rapidly increased, and by degrees the electric current was applied to motive power, and now not only are stores and dwellings lighted by this means, but electricity is applied by the Sprague motor to the running of printing presses and elevators, passenger and freight, fans for hotels and restaurants, automatic ventilators, etc. To meet the growing demand, electric motors have been improved until from a capacity of a half-horse power they have been increased to 10 and even 20 h. p. So general has the employment of electricity become that the Edison company, to provide for the future, is now laying underground wires throughout its domain. The mains will permeate every street where the light is demanded, and soon this mode of lighting will be distributed at moderate cost. Provision is being made for 10,000 lights, and to meet further prospective demands a building is being put up in Head place, from which 40,000 lamps will eventually be lighted. A brick smoke-stack, large enough to serve boiler for 2,000 h. p., will be built, and twenty engines and fourteen boilers will ultimately be employed in generating the electricity.

Incandescent lamps of various candle-power can be furnished, and the charge is in proportion to the power. For each 10 candle-power lamp the charge is three-quarters of a cent for each hour that the lamp is in use, and for lamps of greater or less power the charge is correspondingly increased or diminished. The basis of calculation is the 16 candle-power lamp, for which the charge is 1 1-5 cents per hour of use. In the language of electricians, the use of three lamps for two hours would be six "lamp hours," as would also the use of six lamps one hour, or one lamp six hours. Some of the largest consumers are the Adams House, 450; the Bijou theatre, 700; the Young Men's Christian Union, 400; and the store of Bigelow, Kennard & Co., 190 lamps.

BOSTON, November 16th, 1886.

CHICAGO.

The Contention Over Telephone Rates at Rochester.—Considerations on the Increased Cost of Service per Subscriber in Large Telephone Exchanges.—A Move Toward Public Electric Lighting by the Chicago Common Council.

THE troubles at Rochester, N. Y., between the people and the telephone company is the same old "cabbage warmed over" question which has agitated the business public of all towns whenever there has been any material increase in the original plant, and especially if the plant was one of those which had its birth in the early days of the telephone, when no one knew what the service would cost, and the question of exchange or no exchange was a matter requiring all the methods known to solicitors to induce people to join.

Take for instance the case of Chicago. When it was first suggested that an exchange would be a convenience—necessity was not then thought of—the general public here scoffed at the idea. The answers to arguments in its favor were such as a past condition of things suggested, and the earnest endeavors of the original projectors of the scheme were laughed and jeered at by many, and more than one personal friend of the promoters went so far as to intimate, without perhaps mentioning names, that "somebody was crazy."

The first exchange in this city was made up of parties *all in one line of business*, a fact which in itself shows how little the public understood the capabilities of an exchange. The promoters of the enterprise, after having labored, wheedled, coaxed, driven, almost bribed the subscribers for weeks, did finally corral eleven banks and bankers into an exchange, and commenced business with a little two-feet square switch-board, modeled after the telegraph plug-board.

After the thing had ceased to be a nine days wonder, and experimental tests had come to be matters of no interest, the actual amount of labor required by business proper was so slight that one person could readily do all the answering and connecting, keep two public library cards busy exchanging books, and take an occasional nap into the bargain, and that person an extremely small and cheap boy.

There was a gigantic profit in a rental of $50 per annum, with certain privileges connected with the American District Service thrown in.

The exchange grew. The switch-board was added to; the one "little boy blue" became an army divided into day and night watches; wires were run to distant parts of the city, and sub-exchanges were added to the system. There were gangs of constructors and gangs of repair men, and a bureau of battery men and inspectors. The list of subscribers now numbered over five hundred, and the directors on looking over the yearly statements were astonished to find that instead of making money they were falling behind, and the service was becoming heavy and slow for want of facilities for handling the business.

Then came the first conception of the multiple switch-board, which eventually relieved the pressure, and right here, during the studies which evolved that invention the fact of the rapidly increasing expense of a growing exchange was first made manifest. Experience alone had taught a curious fact, simple enough when found, yet something peculiar, and this is it: Every new subscriber adds to the previously possible connections as many connections as there were subscribers before his admission. To illustrate this, suppose we have an exchange of 5,000 subscribers. The addition of the last subscriber gives as the total number of connections possible the number of subscribers multiplied by itself less one, the last man in, or: 4,999x5,000 — 24,995,000. He has added 4,999 possible calls which he may make, and 4,999 possible calls upon him may be made. Now take an exchange of three times that size, and the addition of one subscriber to an exchange of 14,999 subscribers gives him a chance to call for each of these, and they in turn may each call for him; and twice 14,999 is the sum of additional "hullos" which this last individual brought into the exchange, has made possible. So that an addition of one line to a large exchange is a very different matter in its consequences from adding one to a small exchange.

Many people say that the telephone business is the only one known in which wholesaling costs more than retailing. Not so. In telephony you get far more than twice the value in a large exchange for far less than twice the money; but it is hard to convince the public of this fact.

Digitized by Google

But the public can be taught. From an original rate of $50 the price has steadily gone up, more being charged as the service became more valuable, and at the same time more expensive, until the price to-day in Chicago is far less in proportion to the value of the service rendered than it was at the low price above named. You pay more, you get much more, and the expense has multiplied very much faster than the rates you are charged.

In the city council the other night, Alderman Lyke had an order approved by the Council, asking an estimate from the city electrician, Prof. Barrett, for an electric light plant which should illuminate the main river and its branches from Chicago avenue on the north to Twenty-Second street on the south. The accomplishment of this end will require about 100 double lamps, with dynamos, boilers, engines, etc., and at least twenty-three miles of wire. These wires will all go underground—Chicago takes her own medicine, every time—and wires above ground appear only at the switch and test boxes on the bridge viaducts. The engine, boiler and dynamo building will be placed, probably, upon the south branch, where Washington street would cross to the west side if there were any bridge. From this point there will need to be a perfect metallic circuit up and down both sides of the river and branches, so that in case of any failure of the line at any point the nearest switch to the break will be turned, and the lights on the intact portion of that circuit will burn until the necessary repairs are made. The wires will cross through the tunnels. But, the council has made no appropriation yet, so that there is no need of any premature worry on that point. By and by, when the time comes, all the companies will have a chance to bid, and chaff and wrangle over the contract, just as often happens in such cases.

CHICAGO, December 16, 1886.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

DISTRIBUTION OF ELECTRICITY BY INDUCTION COILS.

[63.]—During the year 1882, being then in Boston, Mass., I carried out a series of experiments upon the use of the induction coil for the purpose of supplying electrical energy from central stations. As a result of these experiments, I made an application to the United States patent office. The application was filed on the 29th of January, 1883, and contained a complete description of a system, in which alternating or undulating currents of high tension, generated in a central station, are used in combination with induction coils which transformed the electric energy conveyed by the mains into a number of currents of low tension and large quantity.

Various arrangements were described and shown in the drawings. The substance of this rather lengthy application may best be seen from one of its claims, which reads literally as follows:

"The combination in a system of electrical distribution of a generator adapted to produce electric currents of high E. M. F., a continuous conductor including the primaries of a series of inductoriums and forming an internal circuit for the said generator; and a series of secondary circuits, each including one or more electric lamps, and formed of the secondary circuits of the said inductoriums, whereby the high tension currents flowing in the main conductors and primaries, are enabled to develop secondary currents of low tension and great volume in the secondary circuits, substantially as and for the purpose described."

The application was rejected; and the objection of the patent office commenced as follows:

"Applicant should demonstrate more clearly to the office, the possibility of producing quantity currents from intensity currents by means of an induction coil; it is not apparent how applicant, in any case, can get more quantity from a secondary coil than he has in his primary."

I now find that a patent has been granted to Messrs. Gaulard and Gibbs, on the 26th of October, 1886, of which the first claim reads as follows:

"(1.) The hereinbefore described art or method of electrical distribution and conversion, which consists in establishing in a closed electric circuit, a current of alternate and equal positive and negative potential, producing by the influence of such current an inductive field of alternate polarity, and thereby inducing in translating devices situated in an independent closed circuit traversing such field, a similar alternating secondary current of greater quantity and less potential than the originating or producing current."

It is quite apparent that the examiner in 1886 had a different view of the function of an induction coil than was the case in 1883.

I may also mention that in my experiments at that time, I made use of a continuous iron core for the induction coil.

In the meantime I have made various improvements in regard to this system of electrical transmission, and I do not intend to relinquish my claim to priority in this matter.

I am sir, your obedient servant, ALEXANDER BERNSTEIN.

THE BERNSTEIN ELECTRIC LAMP COMPANY, Limited.
London, November 18th, 1886.

ALTERNATE CURRENT DYNAMOS.

[64]—I notice in the ELECTRICIAN AND ELECTRICAL ENGINEER, of December, an account of the Westinghouse Electric Lighting System, and mention of my alternate current dynamo. While engaged in developing some of the "modifications" of the Westinghouse system, I determined to design a constant E. M. F. dynamo of the alternating type, having from 16,000 to 20,000 reversals per minute. There seemed to be a general opinion that an alternating current dynamo with an iron-cored armature would result in failure, as the cores when subject to 16,000 reversals of polarity per minute would heat too greatly for practical use. It was found upon trial, that the iron core instead of heating from self-induction, reduced the self-induction to a practical zero. That the great number of reversals per minute did not increase the magnetic lag; and that the calculations used in determining the electrical data of direct current machines were applicable to dynamos of the alternating type.

It was also found that these machines would join in multiple arc with one another, and that they could be connected in parallel with far greater safety than the ordinary commutating dynamos. Two machines were fed into the same circuit under the following varying conditions:

1st. Two similar dynamos driven from a common shaft by belts, synchronized without difficulty when their E. M. F.'s were equal.

2nd. Two dynamos separately driven from separate engines synchronized where the E. M. F's were equal.

3d. Two dynamos driven either separately or from a common shaft synchronized at widely varying E. M. F.

4th. It was found impossible to "leave out" an armature of either dynamo if the fields of the machines were charged.

The demonstration of these points was entrusted to Mr. O. B. Shallenberger, who worked out the clear results with rare judgment and success. Unquestionably the use of iron, of very low magnetic resistance in the armature core, is a large factor in the accomplishment of the above results. It seems likely that this dynamo may form the nucleus of a distinct type of generators.

W. STANLEY, JR.

GREAT BARRINGTON, Mass., Dec. 11th, 1886.

[65]—In an editorial notice of an important paper on the predetermination of dynamo characteristics, read by Mr. Kapp, at the opening session of the Society of Telegraphic Engineers, the London *Electrical Review* says: "A fortnight ago we published a paper by M. Marcel Deprez from *Comptes Rendus* on this very subject; and although in some of his claims of priority, he is, as is not unusual, a little late in the day, the paper should receive careful attention in connection with the subject under discussion"

* * * "There is one statement in this paper of M. Deprez's to which we venture to allude, as it involves a question of priority of invention or discovery, or at any rate of application, which we are now in a position to settle, thanks to the letter of Messrs. Mather and Platt, published in our last issue. M. Deprez, in the article alluded to, says: 'I was the first to construct very thick and short electro-magnets (experiments in the depot of the Northern Railway of France in February, 1883), instead of employing electro-magnets of small diameter, long and numerous, as was done in the Edison machine which figured at the exhibition of 1881. My example has been followed with full success, and the magnetic field of the Edison machines since constructed has been considerably improved simply by decreasing the length of the electro-magnets and thickening the core.'

"We quote the passage in its entirety, because it is desirable that M. Deprez should be allowed to state his own case. We, in England, have been in the habit of connecting the improvement of the Edison dynamo with the name of Dr. Hopkinson, and, as we now know, with perfect justice. For it appears from the letter of Messrs. Mather and Platt, that as early as the autumn of 1882, Dr. Hopkinson first experimentally demonstrated the advantages of the altered form of the magnetic circuit of the Edison dynamo; that early in December of the same year he gave instructions for a dynamo on the improved lines which was constructed and tested with most satisfactory results early in January, 1883; and that machines involving the improvement were actually delivered for commercial use in the following March. Our readers will doubtless recollect that this matter was first

Digitized by Google

given public prominence by Dr. Hopkinson in a lecture at the Institution of Civil Engineers on April 5th, 1883,[1] at which time M. Deprez had not, so far as we are aware, made any announcement on the subject. We therefore see that the example which M. Deprez correctly says 'has been followed with full success' is certainly not that of M. Deprez; although we are quite willing to allow him the degree of merit to which, according to his own statement, he is fully entitled, namely, that he was only a few months behind Dr. Hopkinson in this matter. And this is no slight honor, and one with which others than M. Deprez must make shift to be satisfied."

It may not be uninteresting to your readers if I recall an incident which has considerable bearing on the above adverse, and (I think) unnecessarily harsh criticism of the distinguished French scientist.

The foundation for the 1,000 light dynamo of Mr. Edison was the first work completed before the opening of the Paris electrical exposition in 1881. It was the last thing put to its intended use. Three weeks before the close of the exposition, a long looked for cable despatch from Mr. Edison told us that, after many experimental vicissitudes, the big dynamo had left New York on a steamer of the Compagnié Transatlantiquè. It arrived duly, and I brought it safely to Paris, and we started to erect it. In the haste of the work an accident happened. One of the heavy magnet cores slipped from the hoisting tackle and fell on the sharp edge of a polar extension piece, and cut through several layers of wire of the field magnet coil surrounding it. Among the curious gazers who quickly gathered to view the scene, was M. Marcel Deprez. As the injured piece lay on the ground, he remarked to me: "It would have been easier to lift a shorter piece into position." "But not one so efficacious perhaps, Monsieur," said I "I beg pardon," said he, "a shorter piece would be better. That long leg must have consequent poles in it." This remark led to an animated discussion in which I mentioned Mr. Edison's often expressed preference for long heavy magnets, containing an excessive amount of iron. After the dynamo was in action, M. Deprez again visited us with M. Tresca, and others who were taking indicator cards of the steam engine driving the dynamo. He again referred strongly (and I thought too contemptuously) to the thin, long legs of the monster which was doing good work and exciting general wonder and admiration, and he proved to me conclusively that consequent poles were being formed. This fact being laid away in the mind of a man engaged at that time in the improvement of the dynamo machine as a means of transmitting electrical energy to a distance, it is not unnatural to suppose it did not take long to ripen into the apple of discord which has so agitated the editor of the London *Electrical Review*, and certain scientific inventors in England.

Very respectfully, OTTO A. MOSES.

P. S.—In the interest of fair play to other inventors, and in this connection, I hope you will publish a letter signed G. E. D.,* which appears in the same number of the London *Electrical Review* with the editorial above referred to on Mr. Kapp's paper.

[*See page 24.—Ed.]

LITERATURE.

CATALOGUES AND PAMPHLETS RECEIVED.

We have received, from the authors, a copy of the important paper on Dynamo-Electric Machinery, by J. Hopkinson, M. A., D. Sc., F. R. S., and E. Hopkinson, M. A., D. Sc., reprinted from the Philosophical Transactions of the Royal Society. We shall reprint this paper in full, with the illustrations and charts accompanying it. We furnish the first installment in the present number.

Massachusetts Institute of Technology. Twenty Second Annual Catalogue of the Officers and Students, with a Statement of the Courses of Instruction, and a List of the Alumni, 1886-1887.

Eighth Annual Meeting of the National Telephone Exchange Association, held at the Southern Hotel, St. Louis, Mo., September 7th, 8th and 9th, 1886.

Transactions of American Institute of Electrical Engineers, vol. iii. May 18th, 19th and June 8th, 1886.

Electrical Accumulators. A Circular of the Electrical Accumulator Co., No. 44 Broadway, New York city. This handsome pamphlet gives a brief account of the invention of the Storage Battery by Planté—and the improvement of Faure, and sets forth the readiness of the company to supply Storage Batteries "combining the invention of Faure and improvements thereon" for a wide range of uses, embracing practically all the leading applications of electricity. The circular is illustrated by a cut showing the general appearance of the standard type of cell made by the company, and designated as "15 A."

The Electrical World, 1874-1887. Under the above title Mr. W. J. Johnston, publisher, sends us an extremely neat circular. It contains a brief account of the growth and development of our enterprising contemporary from small and discouraging beginnings to its present prosperous condition. Illustrations of the present tasteful rooms occupied by the various departments of the *Electrical World* are given. Mr. Johnston and his associates are to be congratulated upon their success.

Catalogue No. 5 of the Clayton Air Compressors, Rock Drills and General Mining Machinery. Clayton Air Compressor Works, 43 Dey Street, New York.

1. *Electrical Review*, vol. xii., p. 302.

The Scranton Board of Trade, Scranton, Pa., publish a report for 1886, with the title, "Powdered Anthracite and Gas Fuel." It contains much interesting matter relating to coal and gas interests, with statistics, as well as a great variety of industrial and social information pertaining to the city of Scranton and vicinity.

ELECTRICAL NEWS AND NOTES.

REPORT ON THE EXPERIMENTS OF M. MARCEL DEPREZ RELATING TO THE TRANSMISSION OF POWER BETWEEN CREIL AND PARIS.

BY M. MAURICE LEVY.

(Concluded from page 464, vol. v.)

Calibration of the instruments of measurement and actual measurement of the resistances.—Since February last, at which date regular work was commenced, the engineers of the North of France Railway and the electricians specially attached to the experiments, executed daily the electric and dynamometric measurements necessary for the determination of the yield obtained, so that the commission found the measuring instruments all ready. Before making use of them it has been necessary to ascertain their correctness, and effect the calibration of each instrument.

This was the first operation: At Creil they had to calibrate—

(*a.*) For the mechanical measurements two dynamometers of White's system, mutually identical and serving to measure the motive work furnished by the two locomotives.

(*b.*) For the electric measurements two amperemeters, with proportional deviations on the Deprez system, intended, the one to measure the current of the rings, and the other the current of the inductors, and a potentiometer on the same system for measuring the difference of potential at the terminals of the generator.

At La Chapelle :—(*a*). From a mechanical point of view a Prony brake to measure the useful work collected.

(*b.*) From an electrical point of view the same instruments as at Creil.

The constants of the galvanometers were determined by Cornu's method, already employed in the experiments at the northern station.

The dynamometers were calibrated by means of Prony's brake.

This verification, the results of which are given in table i., showed the perfect accuracy of the measuring instruments employed, as well as of the special co-efficients of each.

The differences between the results obtained by the commission, and the mean results of the numerous observations executed daily by the engineers attached to the inquiry fall throughout within the limit of errors of observation.

The exactness of the instruments being recognized, we measured the resistances of the machines and the line, using the ordinary method with Wheatstone's bridge. The results are given in table ii.

Practical experiments in transmission.—These preliminary operations having been completed on May 24th, one party of the sub-committee went to Creil and the other party to La Chapelle to make the experiments on transmission. The results are to be found in table i. We operated by varying the speed of the generator from 168 to 218 rotations per minute; its electromotive force varied from a minimum of 4, 887 volts to a maximum of 6,290 volts

The power consumed at Creil varied (omitting fractions) from 67 to 116 h p., and that recovered at Paris from 27 to 52 h. p.

The yield increases with the power transmitted.—The industrial yield has varied from 40.78 to 44.81, or about 41 to 45 per cent. With the exception of a slight anomaly in experiment 3, it increases with the horse-power transmitted, which depends on sensibly constant losses, such as those necessitated by the magnetic fields, which are like the general outlay of the operation. They become less and less sensible as we operate on a larger scale.

Thus the most important experiment, in which we took 116 h. p. at Creil and recovered 52 at Paris, was the one which gave the greatest yield, 45 per cent. The fact that we can thus practically transmit 116 h. p. to a distance of 56 kilometres and derive an industrial yield of 45 per cent., accurately measured, not exceeding a velocity of 218 rotations of the generator, and this continuously, without straining the machines, is an extremely remarkable result which could not easily be expected and which must be emphatically pointed out.

Discussion.—It is not sufficient to establish the bare fact of a yield of 45 per cent. It is necessary to find out how the 55 per cent. of force lost was consumed. It was evidently lost, partly by the machines and partly by the line.

Work absorbed by the generator.—The work communicated to the generator was 116 h. p. The difference of the potentials at the terminals of the machine is 6,004 volts. The intensity of the current is 9.789 amperes.

The available work at the terminals of the generator is

Digitized by Google

therefore, expressed in horse-power

$$\frac{6004 \times 9.879}{75 \times g} = \frac{6004 \times 9.879}{735.66} = 80.4 \text{ h. p.}$$

The loss of work in the generator is, therefore, 116 — 80.4 = 35.6 h. p.

Work absorbed by the recipient.—The differences of the potentials at the terminals of the recipient is 5,456 volts; the strength of the current there is 9.824 amperes; the work which the recipient receives, expressed in horse-power, is therefore :—

	Horse-power.
$\frac{5456 \times 9.824}{735.66}$, or say	73.1
The useful work recovered at its exit is	52.1
Work lost by the recipient	21.0

Work absorbed by the line.—The available work having been found :—

	Horse-power.
At the terminals of the generator	80.4
At the terminals of the recipient	73.1
The work lost on the line is	7.3

But the figure obtained in this manner would not merit any confidence. In fact it results from the difference of two very large numbers. However little we may have been deceived in the observations relating to each of them the relative error committed in their difference may be of the same rank as the difference itself. This is the more true as we must remember that all the measures taken are industrial, and not measurements of precision.

It is, therefore, indispensable to determine the loss of the line directly. The loss in horse-power is the product of the resistance of the line and of the square of the mean strength of the current divided by 75 *g*.

The resistance of the line (table ii.) being 95.45 ohms and the mean current (table i.) 9.85 amperes, the work sought for is

$$\frac{97.45 \times 9.85^2}{75.\ g} = \frac{97.45 \times 97.02}{735.66} = \frac{9454.60}{735.66} = 12.7$$

in place of 7.3

found above, or a difference of 5.4

The total loss determined by the dynamometer and the brake being 116 — 52 — 64 h. p., the total loss by the machines must be 64 — 12.7 — 51.3 h. p. in place of 56.6 h. p. determined electrically.

If we share this difference between the two machines we shall arrive finally at the following figures :

	Horse-power.
Loss in generator	$\frac{35.6 \times 51.3}{56.6}$ = 32.2
Loss in recipient	$\frac{21.1 \times 51.3}{56.6}$ = 19.1
Loss in line	12.7
Total	64.0

We thus see that the loss in the line is trifling, and that the machines consume the most of the power. Hence we are led to put the question, what is the industrial value of the machines constructed by M. Deprez? To render the discussion definite, we must especially consider the machine at Creil as being the most important in dimensions and that which best answers to the present ideas of the inventor, and we shall discuss the most important experiment, that which consumed 100 h. p. at Creil.

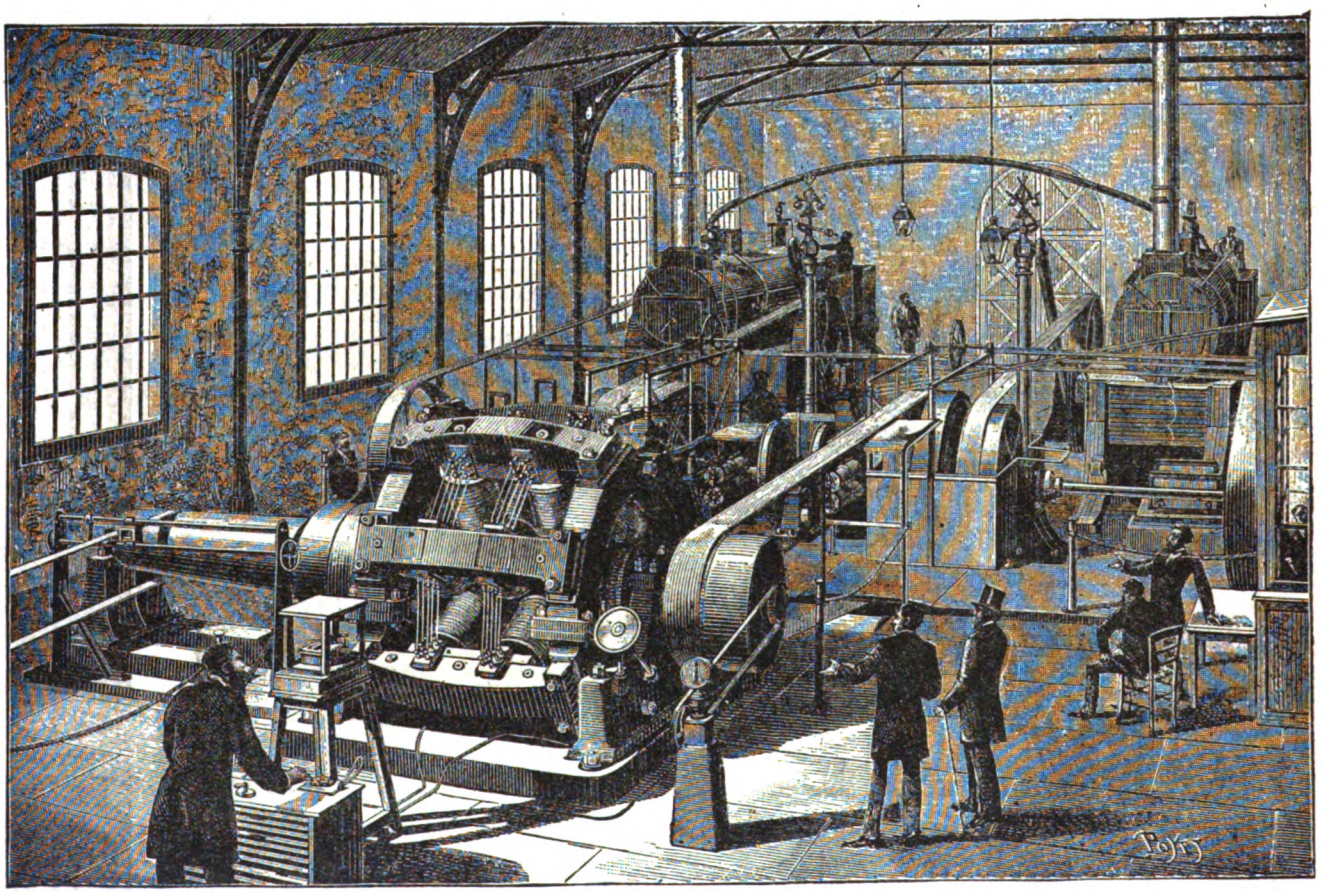


FIG. 1.—MARCEL DEPREZ'S EXPERIMENTS BETWEEN CREIL AND PARIS.—THE GENERATING APPARATUS AT CREIL.

Examination of the industrial value of the Creil machine.—Such a machine may be considered from four points of view :—

1. As regards the qualities of its inductors or of its magnetic field.
2. As to the qualities of its rings.
3. As to the qualities of the entire machine or of its industrial yield.
4. As to its mechanical qualities.

These latter qualities we have recognized by the facility of constructing and repairing the machine, its massive dimensions and the slowness of its movements. We need not return to this subject.

Economic value of its magnetic field.—If we cause a wire to move in a magnetic field of the length of 1 metre, at the rate of 1 metre per second, there arises in it an electromotive force which may serve as a measure for the intensity of the field.

It is merely requisite to multiply the number of volts which constitute this electromotive force by 10^4 to have the measure of the field in centimetre-gramme-second units.

But the intensity alone does not constitute the economic value of a magnetic field. Its volume intervenes likewise, in the magnitude of the effects which may be obtained. This volume in a

Digitized by Google

dynamo-machine is comprised between the two concentric cylinders which limit the inductors and the cores.

In the Creil machine, the distance, between the cylindric surfaces limiting the inductors and the core of the armatures is 0.06 metre. The mean circumference of the annular volume occupied by the field has a diameter of 0.74 metres. The breadth of the field of each ring, equal to the breadth of the core of the ring, is 0.40 metre. Hence the volume of the fields of the two rings is

$$v = 2 \times \pi \times 0.74 \times 0.06 \times 0.40$$

or v = 111 cubic decimetres approximately.

On the other hand, always taking the most important experiment that where 116 h. p. is consumed, the electromotive force developed by the field in the ring of the generator is 6,200 volts, the speed being 218 turns per minute.

The ring is divided into 196 sections; or one of the halves comprised between the brushes $\frac{196}{2} = 98$ sections, having each 20 metres of useful wire (50 strands of 0.40 metres in length).

The total length of useful wire is, therefore,

$$98 \times 20 = 1{,}960.$$

The mean circumference described being 0.74 metre in diameter or 2.32 metres in circumference, the surface described by the wire in a rotation of the ring is

$$1{,}960 \times 2.32 = 4{,}547 \text{ square metres, or for the two rings}$$
$$2 \times 4{,}547 = 9{,}094 \text{ square metres.}$$

As the speed is 218 turns per minute, the surface described per second is

$$\frac{9{,}094 \times 218}{60} = 33{,}041 \text{ square metres.}$$

The electromotive force being 6,290 volts, we obtain per unit of velocity

$$\frac{6{,}290}{33{,}041} = 0.190 \text{ volts.}$$

Therefore, in centimetre-gramme-second units the field is

$$H = 0.190 \times 10^4 = 1{,}900 \text{ units.}$$

Let us now value the crude force which must have been expended to obtain it. The experiments (table iii.) show that with a current of 36 amperes in the exciter, a current very close to that of 36.30 existing in the magnetic field relating to the transmission experiment which we are examining, the work observed at the dynamometer necessary to set the exciter in action has been 12.68 h. p.

Thus, in fine, the Creil generator yields a magnetic field of 1,900 units of the volume of 111 cubic decimetres by means of 12.68 h. p.

Comparison with the magnetic field of the Gramme machine (model A.)—Let us make the same calculation with the Gramme machine. To obtain a field of 1,900 to 2,000 units, there is required in this machine a current of 20 amperes traversing an inductor circuit, the resistance of which is 0.6 ohm.

The work expended is, therefore,

$$\frac{0.6 \times 20^2}{75g} = \frac{0.6 \times 20^2}{736} = 0.326 \text{ h. p.}$$

The dimensions of the field in the Gramme machine are the following:—

Annular thickness of the field,	0.01 metre.
Mean length of circumference,	0.55 "
Breadth of the iron core,	0.10 "

and hence for the volume of the field,

$$v = 0.55 \times 0.10 \times 0.01 = 0.55 \text{ square decimetres.}$$

or about $\frac{1}{200}$ of that of the Creil machine.

Therefore, to produce a field of the same strength and volume as that of Creil, 200 Gramme machines would be required.

As each of these expends 0.326 h. p., the total power required would be

$$200 \times 0.326 = 65 \text{ h. p.}$$

in place of the 12.68 h. p. consumed at Creil. Five times more power would be required.

Besides the weight of the copper in each Gramme machine of the A model is about 30 kilos., the consumption of copper, therefore, would be 6,000 kilos. in place of the 2,534 kilos. required in the Deprez machine.

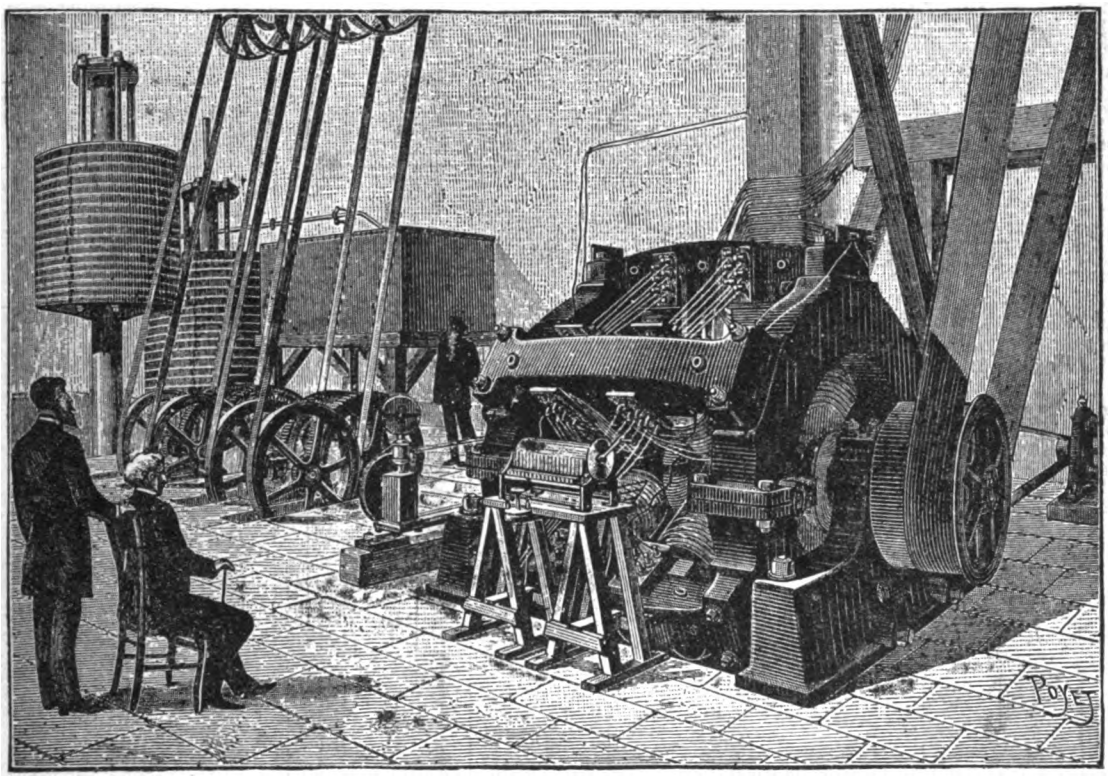

FIG 2.—MARCEL DEPREZ'S EXPERIMENTS BETWEEN CREIL AND PARIS.—THE RECEIVING APPARATUS AT LA CHAPELLE, PARIS.

We see, therefore, that as regards the creation of the magnetic field the large inductors employed by M. Deprez are exceedingly advantageous.

2. *Value of the copper rings.*—The ring of a dynamo machine is so much the more perfect as there is produced less parasitic work, *i.e.*, work other than that which may be collected at the brushes. Such is the work absorbed by Foucault currents in the iron cores and by phenomena of self-induction produced twice in each revolution in each section of the ring.

But there may be other causes of loss of work which have not been analyzed, or resulting from faults of construction in the ring.

Let us call T_i the work thus lost by known or unknown causes; T_m the crude motor work furnished and measured at the dynamometer; T_e the portion of this work devoted to the exciter; T_f that consumed by passive mechanical resistances, such as the friction of the axle of the machine and of the brushes, stiffness of the driving belts, vibrations, &c.

The value of the work really supplied to the ring is

$$T - T_e - T_f - T_i.$$

But this work, as we know, is equal to the product of the

Digitized by Google

electromotive force and the current divided by 75 g or $\frac{E\,I}{75\,g}$.

We have then in strictness

$$T_m - T_e - T_f - T' = \frac{E\,I}{75\,g}$$

whence

$$\frac{\frac{E\,I}{75\,g}}{T_m - T_e - T_f} = I - \frac{T'}{T_m - T_e - T_f}.$$

If the ring were perfect, and if none of the parasitic work designated by T_i existed, the first quantity would be unity.

The value of this first quantity, always less than unity, is that commonly called the *coefficient of transformation of the machine*, and might be more correctly named the *yield of the ring*. The ring is, indeed, so much more perfect the nearer this value approaches to unity.

Let us establish, as we have done for the magnetic field, a comparison between the ring of the Gramme machine (model A) and that of Creil.

The electromotive force of the Creil machine, expressed in horse-power, is $\frac{E\,I}{75\,g} = \frac{6{,}290 \times 9{,}879}{735.66} = 84.5$ h. p.

The motive power is

$$T_m = 116 \text{ h. p.}$$

On the other hand (table iii.) at a speed of 208 revolutions, the work absorbed by friction (open circuit) is 9.38 h. p., which for 218 revolutions will be

$$T_f = \frac{218}{208} \times 9.38 = 9.85 \text{ h. p.}$$

The work absorbed by the exciter in action (with the current of 36 amperes, which is approximately that of our experiment) is

$$T_e = 12.68 \text{ h. p.}$$

whence

$$T_m - T_e - T_f = 116 - 12.68 - 9.85 = 93.47$$

and for the co-efficient of transformation

$$\frac{84.5}{93.47} = 0.90$$

Comparison with the Gramme ring (model A)—The machine, model A, according to the experiments made at the 1881 exhibition by MM. Tresca and Poitier, gave an analogous yield.

Hence it results that the Creil ring, notwithstanding its large dimensions and the great length of wire contained in each section, and which might seem likely to increase the phenomena of self-induction in an excessive proportion, is as perfect as smaller rings.

In fine, like the production of the magnetic field, the arrangements adopted by Marcel Deprez are highly advantageous; on the other hand his ring furnishes the same yield as that of the Gramme machines (workshop model), and that with a much less velocity and great convenience for construction and repairs.

3. *Industrial yield of the Creil machine.*—After having studied each of the two parts (inducers and armature) of the Creil machine, let us take it in its totality so as to show its effective yield.

We define generally the yield of a dynamo machine by the ratio.

$$\frac{\frac{E\,I}{75\,g}}{T_m}$$

of its electric work to the motive power supplied to it. This yield, in the experiment before us, would be

$$\frac{84.5}{116} = 0.725$$

or about 0.73.

But what concerns the industrialist is not the electric work of a generating machine, but the work collected at its terminals compared with that supplied to it. The yield thus understood—the least favorable case which can be considered—is the ratio.

$$\frac{\frac{\varepsilon\,I}{75\,g}}{T_m} = \frac{6004 \times 9.879}{735.66 \times 116}$$

ε being the difference of potential at the extremities of the machine.

We obtain here 0.70, or about 30 per cent. of loss. This figure is probably excessive, since, on calculating the loss due to the line, we have seen that the losses due to the machines are, in fact, a little less than those appearing from the electric observations.

We have found that the loss of the generator is 32.2 h. p. out of 116 received, or

$$\frac{32.2}{116} = 27.7, \text{ or say 28 per cent.,}$$

which would leave a yield of 0.723, or about 72 per cent. The engineers of M. Deprez have found 73 to 74 per cent. Let us admit the maximum loss of 28 per cent.; it is distributed thus:—

Of 116 motive h. p. supplied 9.85 have been lost in friction, stiffness of driving-belts, &c., 12.68 are expended in moving the exciter; the surplus is transformed into heat upon the ring.

Hence the losses incurred at the generator may thus be summarized.

	Per cent.
1. Mechanical losses (friction, vibration, &c.),	8.5
2. Power spent in producing magnetic field,	11.0
3. Heating of the ring,	8.5
Total,	28.

Industrial yield of the machine at La Chapelle.—For a recipient the industrial yield (understood also in the least favorable sense) is the ratio of the power which it absorbs at its terminals to that which it furnishes to the brake on the axle of its ring. The numerical results of table i. indicate, in the experiment in question, that the yield thus understood is 76.5 per cent.

Industrial yield of the two machines connected.—From the dynamo-metric experiments there appears with certainty a loss of 64 h. p. And as the line absorbs 12.7 h. p., the two machines together absorb 51.3.

NOTES.—A deflection of 1° of the galvanometer signifies K amperes.
A deflection of 1° of the potentiometer signifies K volts.
The formula $T_m = \frac{x\,y}{216}$ results from the calibration of the dynamometers.

Hence, it results that in any transmission of power, however trifling the distance, from the mere fact that we are obliged to employ two machines we cannot, with the speed of 200 rotations admitted at Creil, an electromotive force of about 6,290 volts and separate excitement count on a yield of more than

$$1 - \frac{51.3}{116} - \frac{64.7}{116} = 55.43 \text{ per cent.}$$

The mean yield of each of the two machines accurately observed is, therefore,

$$\sqrt{0.5543} = 74 \text{ per cent.}$$

which is sensibly comformable to the result obtained for each of them.

From the yield of 0.5543, or in round numbers 55 per cent. furnished by the two machines connected, it is necessary to deduct in each case the work lost on the line.

Conclusions.—1. We may now affirm the possibility of transmitting with a single generator and a single recipient to a distance of 56 kilometres an industrially utilizable force of about 52 h. p. with a yield of 45 per cent. without exceeding a current of 10 amperes, an angular speed of 216 revolutions per minute or a circumferential speed of 7½ metres per second.

If we take account of the power absorbed by the dynamometers and other instruments of measurement, by the driving bands and the appliances arranged with the view of facilitating the experiments or of ascertaining the best proportions to be adopted for the organs of transmission, all matters which would not exist in industrial applications, we may say from the present that in practice the yield will be very close upon 50 per cent.

Of the loss of 55 per cent. the two machines with their exciters have absorbed about 45 per cent., and the line about 10 per cent.

In any case the line will absorb more or less according as a thicker or thinner wire is employed.

If we have abundance of cheap power at command and consequently do not attach much importance to the yield, we employ a thin wire which will render the installation more economical, but will absorb more power.

If, on the contrary, the power at disposal is limited, and it is requisite to draw from it the greatest possible advantage, economy in the first outlay must be sacrificed by adopting a thick wire. Here is an ordinary problem for the engineer to solve, according to the circumstances of each case.

2. The working of the machines is now exceedingly satisfactory, both as regards regularity and continuance.

Since February they have been worked for a mean of five hours daily, and up to nine hours without serious heating, burning the wires or producing sparks at the brushes.

3. The speed of the generator when consuming 116 h. p. is only 216 turns per minute and that of the recipient 295 turns. These are industrial speeds with which we could scarcely expect to produce so great effects, and it is a striking sight to see a dynamo moving so slowly and yet so powerful, that at each rotation of its rings mechanical power of 1,000 to 1,200 kilogrammetres becomes industrially available at the distance of 56 kilometres.

4. The maximum electromotive force is 6,290 volts.

The danger resulting from the employment of such potentials is one of the principal objections which are urged against these experiments as regards their application to ordinary practice.

We believe that this is a prejudice which should not be allowed to become established.

The experiments at Creil have lasted for more than six months; it is the first time that the persons employed have had to manage such potentials and yet we have not had the slightest accident to deplore; which proves that with due precautions the dangers may be overcome.

Besides, all human industries, without exception, are full of dangers, especially in their commencement.

As they are developed the danger declines, though without ever disappearing. There are always junctures where fatality will triumph over human foresight. These sad moments man accepts as episodes without influence upon the main result of his struggle against natural forces.

The catastrophes which, in spite of the improvements adopted, still meet us in the two greatest industries of the world—in railways and in navigation—hinder no one from profiting by their benefits.

It will be the same for the transmission of power if it gives the results which we are now permitted to hope.

5. Another fear inspired by the use of high potentials, springs from the losses of electricity, which they may facilitate on the way.

Experiment, which alone can here decide, has not justified these fears which theory rendered admissible.

In all weathers the resistance of the line has remained approximately constant at equal temperatures, and the difference of the currents of Creil and of La Chapelle has always been very slight. This may be judged by the figures in table i.

6. If we admit a velocity of 300 turns in place of 200, which appears quite feasible, and which in the conviction of M. Deprez can be widely realized, we may, without even increasing the electromotive force, gain considerably in the yield simply by diminishing the resistance of the rings.

M. Deprez thus hopes to exceed the yield of 50 per cent. which he announced at first.

The more decidedly will this be the case if we agree to increase the electromotive force, which can be done without augmenting the weight of copper of the machines and without altering their speed. M. Deprez regards such a result as realizable. But on this experiment has not yet decided.

7. As regards the wire, the commission considers that it may be left bare for its entire length except at its entrance into and its exit from the workshops, provided that it is everywhere conveyed out of reach of the hand and at a distance of at least three-quarters to one metre from telegraph or telephone wires, so that

Digitized by Google

whatever wind may prevail, it cannot be entangled with them nor produce upon them any effect of induction.

8. The cost of an installation of transmission cannot, of course, be founded upon the expenditure incurred in the experiments where everything had to be created. The commission has nevertheless obtained information on the transmission of 50 h. p. between Paris and Creil from data furnished by these experiments.

It appears that the price may be fixed thus :

	Francs.
Generator machine,	50,000
Recipient machine,	30,000
Line 56 kilometres, estimated at 800 francs per kilometre going and returning,	44,800
	124,800

This price has been given as a simple indication. M. Deprez considers that it will be signally diminished in consequence of the regular manufacture of the machines, as also by important improvements which he calculates on introducing, taking into account the instruction derived from the present experiments.

9. From a scientific point of view these experiments seem to reduce to nothing, or to a mere trifle, the effects of self-induction which seemed likely to result from the sudden changes of polarity produced twice per revolution as each wire passes by the brushes. They show, also, that with careful construction Foucault currents may be avoided, even in the largest machines.

Lastly, they confirm the laws of electro-dynamic induction far beyond the limits reached in former experiments.

I add that the report of the commission concludes with these words: "The commission, in the name of science and industry, warmly congratulates M. Marcel Deprez on the admirable results which he has obtained. It expresses its gratitude to MM. de Rothschild for the exhaustless generosity with which they have supported this gigantic experiment."

Wrapping of fine wire	27.81	"

After this report had been read, M. Deprez thanked his colleagues, MM. J. Bertrand, E. Becquerel, and A. Cornu, for the active part they have taken in the researches of which M. Lévy had just given so clear and thorough an analysis.

He took, also, the occasion of expressing his obligations to his coadjutors M. Sarcia, the engineer charged with the construction of the machines, and the direction of the station at Creil; M. Geraldy, engineer of bridges and highways, who was charged with the direction of the station at Paris; M. Minet, charged with the graduation and the control of the instruments for electric measurement; MM. Duché and Clémenceau who superintend the measurements and the inspection of the machines.

He also expressed his gratitude to MM. de Rothschild, without whose generous assistance so extensive an experiment could never have been made.—*Comptes Rendus.*

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.
SPECIAL MEETING AND DINNER.

The second dinner and special meeting of the season was held at Cable's restaurant, No. 130 Broadway, New York city, December 7. In the absence of Mr. F. L. Pope, president of the institute, Capt. O. E. Michaelis, was voted chairman. After an hour and a half of social enjoyment, including a very good dinner, the chairman called the meeting to order, promising an intellectual treat in the paper of the evening, by Mr. T. Commerford Martin. Mr. Martin then read his paper, the subject of which was "Electric Street Cars" [see p. 15]. When Mr. Martin had finished reading, Capt. Michaelis said:

Gentlemen: I am sure that we have all listened with great pleasure and profit to Mr. Martin's exceedingly interesting, simple and lucid paper, and I now declare the subject open for discussion. In connection with that I desire to say that under the rules of our society we should be very happy indeed to hear from any of our guests here this evening who are not members.

Mr. Murray Mitchell—Although I only came in at the end of the dinner, I have been extremely interested, and have listened with great attention to everything that was said by Mr. Martin, and I have only risen for the purpose of corroborating what he has said in relation to the Baltimore road and also to direct your attention, and I think perhaps also his, to the fact that in the comparison shown in his report between horse-power and electricity, the comparison of $6.50 to $4 is not as advantageous to electricity as it should be; because the average speed which is accomplished there with electricity is eight miles an hour, and the speed which they formerly had was only four miles an hour; which of course reduces the cost in comparison—so that the cost of electricity should be put at about $2 as against $6.50 instead of $4 as against $6.50. That I know has not been brought out by Mr. Martin's report directly, but I think it worthy of attention.

I should also like to state that as counsel for the Safety Electric Railway and Power Co., which operates under the Daft patents, I had the pleasure some two months ago of closing a contract in Pittsburg for the equipment there of a railroad to be two and a half miles in length, where the grade is 14 per cent. going up one of those terrible Pittsburg hills. We first thought of equipping it without any safety device, relying merely upon the traction attained by electricity and the weight of the motor; but as there happened to be a curve with a 50 foot radius on the grade of some 700 feet to the mile at that point, and as this happened to be on an elevated structure, something like our elevated roads, and as the danger, if there should be any slip of any kind in going around that curve would be very great and would result probably in great loss of life, we thought it better to adopt a system which Mr. Daft himself examined and approved of, using a species of cog rail but doing away with the old form of cog. It answers the same purpose without having the disadvantages and expense of the old system. That road I think will be fully equipped by the latter part of March, and probably be running at that time. We have there the underground conduit, which is being constructed by Mr. Wharton, of Philadelphia. He has built a great many cable roads. We have there a very strong form of conduit, it being formed of slot rails, seven inches in height and supported by ties and also by chairs, which are made very heavy and were almost strong enough to hold firmly the slot rails without any other support. This road also has the overhead system, making a combination of the two which has not previously been tried in this country; and I hope that at the time that that road does run I may have the good fortune to see many of the gentlemen present out there, and have the pleasure of taking them on the first ride.

Mr. Wetzler—Mr. Martin has remarked in his paper that one of the principal points to be considered was the coal bill. It is interesting, therefore, to note that in the Julien Electric Railway at Hamburg, a calculation has recently been made on the basis of 1,600 kilometres run: that is, equivalent to about 1,000 miles. Mr. Huber, the engineer there calculates that for the 1,000 miles run the power required to propel the cars one kilometre is, on the average, three-fourths of a horse-power an hour. Now, that figures out in this way. If it takes three-quarters of a horse-power an hour to propel a car one kilometre, and assuming that three pounds of coal per horse-power per hour is what a fair average engine will do, then the coal required to propel the car one mile would be three and a half pounds of coal per mile. Now, take, for instance, the Third avenue road in New York; on a basis of three and a half pounds of coal required to propel a car a mile, we would have, assuming there were 300 cars—I think Mr. Martin puts it at 360—say there are 60 extra cars, which are either summer cars, or cars laid off for repairs—that would give 175 pounds of coal per car per day. I am basing that on a run of 50 miles of car per day. That would give 52,500 pounds of coal a day, or 26¼ tons. Calculating a ton at three dollars we should have for the coal bill alone per day only $78.75—and that is with accumulators.

The Chairman—Gentlemen, we have present a number of distinguished men, well known in connection with the subject that we are studying, and I am going to take the liberty of calling upon some of them. First, I will call upon a distinguished foreign gentleman who is with us, whose name has been specially mentioned, as familiar to us all, Mr. Julien, and we would be glad to hear him speak on the subject. There is one of our members present who would be very glad indeed to interpret what he may say, in case he will favor us.

Mr. Julien was warmly received and addressed the meeting in French. Mr. Mailloux translated the remarks of Mr. Julien to the meeting, as follows:

Mr. Julien expresses his thanks and his great gratitude for the honor conferred upon him, and wishes to say that as Mr. Martin has entirely covered the points in his paper, it is scarcely necessary for him to elaborate them further, and that he could only speak of personal matters if he were to attempt to discuss the subject, which he thought might perhaps not seem acceptable. Upon assurance that that would not be the case he continues. The circumstances under which the tests were made at Antwerp were such that they represented an almost inimical feeling to the

Digitized by Google

question of electrical traction by any process whatever. During the six months that the tests lasted, every detail of the system was subjected to the closest scrutiny; the accumulator cells were sealed, and they were kept almost under lock and key; he was scarcely allowed himself to look at them. The tests were made by judges, the most competent engineers and electricians, and they were made with every precaution that might be necessary to prevent any tampering with the regular order of procedure, and there was a feeling which was quite current in general engineering circles, and also on the part of electricians, that there was not much reliance to be placed upon electrical traction, particularly by accumulators, that even electricians themselves were in such an infantile state of evolution that it might be well enough to wait until they had grown a little farther, and as to accumulators it would be well enough not to think of them for some time.

Referring to the statement made by Mr. Martin, and the assertion made by Mr. Wetzler, that the cost of energy necessary for electrical traction is three-fourths of a horse-power per kilometre, and as the energy required for the lamps must also be counted in, say 10 cents a day, the total expense of about three dollars would be necessary for the energy actually needed, and counting an expense of two additional dollars for all other costs of maintenance and wear and tear and interest and various other expenditures, we would arrive at the cost of five dollars which has been mentioned by Mr. Martin. The cost was thus found by the experiments made at Antwerp, and that cost might be considered so to speak historical; it might be conceded to be the cost on which we could safely calculate the probable expenditure of running the electrical car.

Desiring to submit the system of electrical traction to the electricians of Paris and to a committee, and to exhibit it there, and let it be tested in order that the figures and statements as to its value might be corroborated and also that the facts as they have been found at Antwerp might be known more generally, a test was arranged for there.

Much opposition was encountered; the French electricians had been preaching against and disparaging the accumulator. Perhaps they had had too much of Mr. Philipart in times past. That may have had something to do with their disgust. At any rate a jury comprising some of the most able electricians was selected. Our endeavor was to place ourselves under exactly identical conditions with the system of electrical traction that was exhibited by the firm of Siemens at the electrical exhibition of 1881, and to make a comparison with that on the score of cost, facility of running and various other conditions; and although the jury comprised men of conservative inclination and disposition like Messrs. Fontaine, Hospitalier, and others, men very well known in connection with the application of electric motors, and although Mr. Fontaine himself took charge of the accumulators and did not let us have anything to do with the manipulation, a despatch was received this very morning stating that the jury at Paris had conceded every point that had been made with them, and that they had found the figures representing the cost at Antwerp, had not even been reached. The actual estimate of cost of running under the conditions at Paris were much more favorable than those arrived at in Antwerp.

The experiment had been going on since last July with two cars; there were two cars in continual operation so that the test could be made very thoroughly, and the expense arrived at very correctly.

Translating the conclusion of Mr. Julien's remarks, Mr. Mailloux said:—Well, gentlemen, I have managed to get along so far pretty well, but I doubt very much, as good a friend as I am of the English language—it is my native language—and as much as I think of the good old Saxon, I doubt if it is adequate to express the very eloquent and beautiful peroration Mr. Julien has just given us; but I will make a feeble attempt. His idea is briefly that he does not wish to occupy your time any longer by talking himself. He does not think it is well for people to say too much of themselves. He thinks he has already taxed your patience and he merely wishes to say that he would be very happy to demonstrate the facts and theory and the system which he is interested in to the satisfaction of all those here present, and that he will consider himself happy if in coming among electricians of an intelligence so developed and of a genius for invention so skilled and so well known as that of America, he has succeeded in contributing one stone to the great edifice of science, particularly in respect to the subject of electrical traction.

I must not forget to mention a significant thing, namely, that Mr. Julien has received two diplomas of honor, one for the car and one for the method of accumulators.

The Chairman—I see present a gentleman well known to all in connection with the subject, whom we desire to call upon—Mr. Van Depoele.

Mr. Van Depoele—Well, gentlemen, I think you know about as much about it as I do. Everything has been stated this evening and I can simply corroborate. Still, there is one little plant that I might give the exact cost of, for the cost is the main thing in the whole business here. We ran a plant in Minneapolis, Minnesota. This is I believe the largest electric railroad ever run in this country or anywhere else so far as I know. We have there about a 60 h. p. motor, and the train consists very often of 90 tons weight, or 91 tons. We have run it for about nine months. I might state also that they have tried a soda motor there, which we will tell about later. But at all events we have been running there at an expense of about 3,000 pounds of coal a day—that is, starting in work at six o'clock A. M. and running till half-past eleven P. M.—and certainly any of the locomotives that used to do the work before consumed as much as four tons of coal a day for the same work, which shows that although we have to transform our power twice, that still we will make a great economy over the ordinary steam engine. Our system is not now running, for the simple reason that some other parties persuaded the authorities there that they were going to bring there for them to use something wonderful in the shape of a soda motor—a soda fountain with a stick in it, or something of that kind! The soda motors came and we went off the track and let them on. But, let me say, those soda motors can hardly pull themselves, and at present are lying there like a lot of old scrap iron in the shops of the railroad. Of course the authorities there would not at the present time like to take back the electric motors for fear of stultifying themselves. But we ran very practically over that route using only very common apparatus. The whole thing was only a common freight car with four ordinary 36 inch wheels, and an ordinary gearing from the motor to the countershaft and from the countershaft to the axle of the wheels of the common car, wearing out only one belt in all that time, and working 18 hours a day, carrying 47 of their regular railroad trains a day. So it was shown that electricity can be used for heavy work as well as for light work.

Another instance where we might give figures—of course all this figuring will come much easier after we have big plants running—is this. We are now putting up a big plant in Montgomery, Alabama, where we have twelve cars running, and when it is all finished we will be able to give the exact cost of running, but so far as we have tried it—and the grades are six and a half and eight per cent. there—in fact there is not a foot of level ground in Montgomery—with two cars we have consumed an average of 1900 pounds of coal a day, so that it costs about five and a half or six dollars a day with the two cars with the engineer's wages. That is a very small plant, and if small plants can do as well as that, larger plants can do much better.

Mr. Julien made some further remarks in French, which were translated by Mr. Mailloux as follows:—

Mr. Julien wishes to ask the privilege of speaking to say that he was ignorant of the fact that a fellow countryman of his Mons. Van Depoele, was amongst us, because he said he would have felt it incumbent upon him to begin by paying tribute to the work of an electrical engineer whose genius he admires greatly.

Mr. Mailloux—Mr. Chairman, I am interested in electrical railway matters just as I am in other branches of electrical engineering such as once in a while come under the province of an expert and have to be investigated. At the same time, while I am watching its development, I like to look at things from a practical point of view. There is a question which is now agitating the minds of practical engineers, and which gives me the opportunity to ask Mr. Van Depoele a question. It is this: There is a great deal of doubt, a great deal of difference of opinion, as to the manner in which the energy shall be applied to the shaft of the motive wheel—the driving wheels. I heard Mr. Van Depoele say that he gears his motor to a countershaft, and that he conveys the motive power from that countershaft to the driving wheel by means of a link belt. Now that link belt is, I understand some to say, a bugbear of the electric railway, or one of them, and I would like to ask Mr. Van Depoele about the length of time that that link belt has been running; also about how much of velocity it will stand safely; that is to say, how many feet per minute will it run without making too much noise or without being strained unduly, and also how long the link belt will last under those conditions?

Mr. Van Depoele—I will be very glad to answer this question, gentlemen. We have some link belts running now for the last eight or nine months on street cars. We have tried several different modes of transmission—to give directly to the axle of the car something which will obviate the vibrations transmitted by the axles running directly over the road. There at once we have a flexible connection between the motor and the driving wheel. The motor can stand on the same body as the car itself, and, consequently, does not participate in the heavy vibrations to which it would be subjected if it were carried directly by the axles of the wheels. Consequently, with street cars that is about the best connection I can find at present. I would like to be understood that any ordinary link belting in the market would not answer the purpose. We have a link belt which we made for the purpose of our business. We have tried the cast-iron link belt and found that to make considerable noise, and to wear out too fast, and not capable of running at a high speed. I have run at thirty miles an hour. I did not formerly believe that a link belt could do the work, but it seems when it is solid and correctly made you can run it at that speed without hurting it. The link belt used

Digitized by Google

by us consists of two side pieces of steel, pressed, and the steel brushing pieces are then fastened to a steel thimble at the upper end. Right through that steel thimble goes a pin. That pin catches the two lower ends of the next link, and consequently there is no friction in the small parts, but the friction is taken by the larger surface of the thimble. Right over the thimble is a steel roller. There is really no wear to the chain. We have had in Windsor, Canada, a chain running there for about eight months, and in fact it is just as good to-day as when first put down. Of course, for running fast we have certainly to use another method.

Mr. Mailloux—At what rate was the belt running?

Mr. Van Depoele—The belt was running then at about the rate, I should judge, of one-third less than that of the wheels.

Mr. Mailloux—Twenty miles an hour?

Mr. Van Depoele—Fully 20 miles an hour; and at the end of the track I stopped to feel whether the belt was hot, and it was not warm at all. Of course, for heavy work and fast speed, I think the link belt would not be suitable. Then you want to have a direct mode of connecting. Certainly, it is very difficult to get a good connection between the motor and the axles of the wheels, because, to make a motor large enough to connect directly with the axles of the wheels without any gearing, the motor has to be made too big. I think it would be out of the question to make it that way for ordinary speeds and bring it within certain limits. But to gear back, of course you have to use some kind of gearing. Friction gear I do not take much stock in. It is not reliable: it wears out, and there is always some trouble about it. Of course, the cog gear is positive, but it makes too much noise. But if you put up gear that is solid and mathematically true, and with good lubrication, I find there is not much noise when the gear is entirely covered up, like the gear we have in Scranton, which you cannot hear. It is boxed well, and works well, and fits tightly; although how long it will last of course we do not know. We have several of them running and they run well. If you gear back at one to eight you will have a good deal of noise; one to four you will have hardly any noise; one to eight there will be big wear; one to ten of course worse. There is a kind of medium between those, and you will have to take your choice in making your proportions; but the link belt, I believe, is the best thing for the street cars to-day, that is, a belt made specially for the purpose.

Mr. Mansfield—Mr. President and gentlemen: I think one of my years should mind the old saying that my father used to hurl at my innocent head whenever I attempted to say anything, to wit, that little boys should be seen and not heard. There are so many older heads and so many more experienced heads in regard to the mechanical and electrical problems, that I feel that I could not say much that would be beneficial. But I certainly would strengthen Mr. Van Depoele's remark that it is a most difficult and exceedingly troublesome thing to find any good method of connection between the motor and the driving wheels. He has spoken of a variety of methods of doing it, and there are other varieties yet of which he has not spoken. He said that the link belt gave a flexible connection between the motor and the driving shaft—that is an excellent plan, and probably would be necessary where you needed a flexible connection. But I would like to bring up just this one point, and that is, that we have before us two distinct fields to labor in. One field is to equip the 20,000 cars already now in this country, running over some 3,000 or 4,000 miles of track, and being drawn by some 125,000 horses, and with the system of construction which now prevails. The street railroad men, of all men, I believe, are hunting not only for a means of propelling their cars, but also they are hunting for a better mode of constructing their railroads. Now, with the present variety of construction of a large majority of the street railroads of this country you would need your flexible connection, and possibly leather belts; perhaps the link belts; possibly a good combination of gears can be arrived at to get this flexible connection. But the other field is the field of new construction, and this field is the field in which I think the electricians should specially labor. They should start now, and not wait five or ten years, but educate the railroad profession, the street railroad men and the street railroad builders,—the street car builders, and show them that their cars and that the street railroads must be built for electric motors. And if then they are built for the electric motors, we can supply them with something which is perfection, which will entirely do away with a great many evils which exist of course with horses, and with every other means of drawing and propelling the cars, even to the cable. The cable has a limited field—it can not operate branches successfully. But with electric propulsion in view in the construction of new roads, there is, owing to the marvelous flexibility of electrical application to street roads, no known difficulty that electric motors and the application of electricity cannot successfully eradicate and overcome. So, I close with this simple thought that if the electric street railroad men and the profession engaged in that work will impress upon the minds of all men interested in street railroads, that their roads in future must be constructed from the very word "go" for the application of electric motors, no matter by what system, but by the application of electricity—then I think, and by that means only, will we come to the general and successful application of electric motors to every street railroad throughout the country.

Mr. Mailloux—There are two points which I wish to dwell upon in what Mr. Mansfield said. I would begin by the last. He speaks of the correct, or evolutionary, method of developing electric railroads as that in which the electrician anticipates all that now hinders and warps him in the development of his problem, by beginning from the very first, from the outset, to prepare the road for electricity. That is a conclusion that has already been arrived at in reference to electric lighting. You will find that in new buildings, the latest large houses, factories, &c., we do not need longer to resort to the laborious process of drawing wires through, or taking them up to the ceiling; but we anticipate by preparing for any system of electric lighting, putting in wires inside of the ceiling during the construction of buildings, instead of having to run them outside afterwards. I wished Mr. Mansfield had permitted himself to go more fully into the subject. He has been intimately engaged in the study of electric railroading for at least four years past, and I do not think there is anybody here who is better posted in regard to the intricate details and complications of the problem than he; and I have heard him particularly speak of that very question of transmitting power from the motor shaft to the driving shaft, and he has made some very pertinent remarks in another meeting before another institute on that subject, and I think it would conduce to the general information of us all if he would briefly review what he said then so that it may come in print with the rest of it. I have reference particularly to the methods he spoke of in connection with round belting.

Mr. Mansfield—Mr. President and gentlemen—I must confess that I am considerably abashed at this method of treatment of Mr. Mailloux, and I did not come prepared to make any remarks at all, but simply to gather in all the points and all the morsels of information which I felt would be distributed and lavished upon all those here with a free hand this evening. On the occasion referred to—at the American Institute, a meeting of the electrical section—I simply gave an illustration by means of diagrams and very casual remarks of the different methods which had been used as far as I was familiar with them; and I can only repeat, if you desire, what I said of the methods presented then; but I do not wish to discuss the efficacy of any single one of them. I mentioned then that the most primal and perfect method obviously would be the application of the armature to the driving shaft direct. That does away with all gearing. That method has been utilized by Mr. Daft in the Enos elevated system. That system has two driving wheels, and the armature shafts extend on each side of the driving wheels, and the armatures are keyed directly on the shafts, and, of course, the periphery of the driving wheel is small. It is figured for a certain speed, twelve to fifteen miles an hour. Of course, the main difficulty which I think there is in using this direct connection, is simply a constructional one as to the electric motor. The ordinary horse-car wheel, if I remember rightly, makes only some 60 or 80 revolutions a minute to accomplish the ordinary speed which is used upon the tramways. Now then, to construct a motor or an armature to go at that slow rate of revolution and develop any power, you would have to go to just the extreme which Mr. Van Depoele mentions, and thus construct a pretty large motor. There is next a simple pinion upon the armature shaft; that running in a large gear which is keyed upon the driving shaft. That method is simple, but it has its objections. Yet, if the mechanical details are properly carried out and well proportioned, I think that a very successful application can be made, even up to as high a ratio as eight to one, or ten to one, in the gearing. That is the application used on the Baltimore road. Worm gear can be used, which is equally as simple as a pinion with a gear; but it is not so economical. The action of a worm in a gear is, we have always been told, a very brilliant method of losing power—that as high as 30, 40, 50, and even 60 per cent of power is lost, due to the friction of the worm within the gear; although Mr. Reckenzaun, I believe, states that he has constructed a worm of a very high pitch and has constructed his gear to match, and that he gets a very low loss, 15 or 20 per cent, if I remember rightly—running in oil. Now, we go from these simple methods to another which introduces one more element, and that is a countershaft. We can drive from a pinion upon the armature shaft to a gear upon the countershaft and then again from a small gear out of that upon a driving axle. Of course, any little gradient or any little difficulties which were apparent would be increased in this case by the introduction of another gear. The noise can be cut down by using leather belting, round, flat or angular; or link belts can be used. These would take the rapid revolutions of the armature shaft and carry them to the countershaft with very little loss and with not much noise, and with very little wear. The flexibility of this system would be between the armature shaft and the countershaft. Of course, there can be modifications of these plans, and I believe that I noticed in the *Electrical World* a description of one used by an inventor out west in which he used a train of gears very similar to the gears that are on lathes in ordinary machine shops. That

Digitized by Google

is Professor Henry, I believe. Now, that, I believe, is the perfection of complication. I have briefly mentioned the various ways with which I am familiar that have been in practical operation. There is one other which I perhaps should mention, a direct running with no intermediate gearing—I ought to have mentioned it first—and that has been brought out by Mr. Stephen Field lately—using a crank shaft on the end of an armature shaft, which is attached to a connecting rod. That certainly does away with all intermediate gearing, and if he can successfully cut down the speed of his armature to apply it to a street car, with all the street car difficulties of going so exceedingly slow—for example, a mule with two tons behind him and a very cross-grained disposition in front, on the track ahead of you—if you can cut it down to that slow rate of speed, of course for tramways there could not be anything much better. But for lighter suburban ways, where you have got the right of way and where you want to run at a rapid rate of speed, where you want to connect two places, one of business and one of residence, where the business man who has been laboring for five, six or seven hours a day at his office and wants to get home at the rate of two miles a minute to see his family and to get something to eat—of course then the direct application is superb.

The Chairman—I believe I voice the general desire in calling upon Mr. Field.

Mr. Field—As to Mr. Mansfield's remarks—much obliged for the compliment—there are two ways to apply the speed of armature necessary. One is to confine yourself to the ordinary two pole machine; the other is to increase the number of poles of that machine. That I have accomplished and with only two brushes. Then again, with regard to the conduits for city traffic, I propose, in introducing a street railroad on a line already established—you know all the rails are laid on a sleeper—to go along and take that out bodily and put in its place a hollow cast-iron girder, the top of which is capped with a steel rail and a flange carried underneath, so that you cannot get a horse's heel into it, but you can have your little carrier in there. Mr. Martin said that such a method involved carrying very high potentials. I propose to carry one or more high potentials, but at the same time have the minimum strain on the insulators, that is, the insulating medium. To accomplish that I establish a power station at each end of the line—running two insulated conductors, one carrying a positive potential and the other a negative potential. You will observe that from these parallel conductors every car will get the same difference of potential wherever it may be on the line. By that means I can carry as high as a thousand volts; and you have got to have that with a great number of cars and moderate size conductors. There is no other way to do it that I can see. Then for very large motors I wish to call your attention to a little improvement. You know how the things will spark unreasonably. I find that the spark is not governed by anything particularly. It seems to vary with the load and with the machine, and with the man that works it. I thought I would let the spark govern itself. I put a couple of extra brushes on the commutator at points of normally equal potential and connect them with a motor called the brush governor. As long as the regular brushes are at the proper point no current will pass from these extra brushes. Let the regular brushes get ever so little out, and immediately the current commences to go through the brush governor and thus turn the brushes to neutrality. The result has been very satisfactory.

Mr. Pendleton—Mr. President and gentlemen—I felt to-night that I as a visitor might occupy the position referred to by an eminent member of a whist club that I belonged to, when he said that the gallery should always be silent..

I am very much gratified at meeting here so many gentlemen I am acquainted with by name more than in person, and gratified also in having heard from Mr. Martin the excellent address which he has given us. But in that address he took occasion to say that those who spoke well of the accumulator had been often looked upon as knaves or fools. As the accumulator and its uses had formed the main subject of my investigations in electricity I felt that, although thoroughly consistent for the last five years in the matter, we had now arrived at a time when we could boldly face electricians and the public with the service and the good service that the accumulator was capable of. It is now some two years since its value in connection with electric traction came to my attention. I have appreciated and understood the remarks of our distinguished guest, Mr. Julien, to-night, a gentleman whose name was thoroughly familiar to me as the associate of Mr. Camille A. Faure, and whose intelligent work in the development and the application of the accumulator to traction was appreciated by us before his arrival in this country. The demonstration that has been made so far has only been thwarted by mechanical and not electrical misfortune. I do not feel that on the subjects to-night, which have been so thoroughly canvassed, I can give you very interesting or pointed remarks. But I will say that the subject of electrical propulsion of railways is now attracting general attention, and our deliberations and the remarks made to-night will go far to instruct the railroad men of America in the fact, which we have known long since, that the electric motor is the engine best adapted for their purposes.

Mr. Mailloux—I would like to suggest to Mr. Pendleton that he tell us something about his system in connection with the accumulators, which he has brought forward and which seems to possess some features of merit, namely, the combined conduit and accumulator system.

Mr. Pendleton—The system which Mr. Mailloux has referred to is a combination of a conduit with an accumulator system for energizing the motor. On nearly all systems of electrical railway there will be a necessity for distribution of passengers at different points; and it occurred to me some time ago to study up the matter in the direction of refreshing the accumulator during service and in the direct transmission of energy from the station to the car. There is always the question of insulation and loss by resistance, which has formed a very difficult problem in many instances to solve, as we know, from results on various railways which have been established in Europe. But, by combining the two systems, convenience and elasticity will be found by taking the current directly from the dynamo where it is the most economical; and over the parts of the line where resistance comes severely into play, the accumulator would afford a means of propelling the car. To illustrate this more fully I should say that in a system where the power station does, through the conducting tracks or conductors, the double duty of actuating the motors and charging the accumulators at the same time, the accumulator itself can be made the means of governing the motor on that part of the line. When passing beyond the limit of the line where conductors exist, the chemical energy stored in the accumulator will operate the motor and at the same time be able to control it. For instance, supposing a line of twenty miles, or any other distance, a station would find difficulty, by the ordinary methods, to operate a motor located in a tram car at that distance, ten miles on each side, from the station. But taking the ordinary conditions of a line, the car would at times take 7 to 10 h. p. upon gradients or curves, while on the ordinary levels 1 or 2 h. p. would be sufficient to propel it. Now, having on the tram-car the battery of accumulators, a simple system of commutating the accumulators into different combinations of two, three and such series would enable the electromotive force—the constant electromotive force—of the line to be varied so that a certain proportion would be used at the motor and the remainder would pass into chemical energy, and by varying in that way in going up a gradient the bulk of the electromotive force would operate the motor. In a down grade the bulk of the electromotive force would pass through the accumulators, and the ordinary accumulator instead of operating the car under such circumstances thirty miles, might be made to operate the car for a day of fifteen hours, as when passing over the portion of the line having conductors the accumulators would be constantly refreshed and upon a combined proportion for the purpose the accumulators would be available almost continually without stopping. That is briefly the system which Mr. Mailloux referred to, and the only matter in addition is the mechanical device which was proposed to be placed under any horse car for the purpose of converting the cars now in existence into electrical cars which would advance the principle more rapidly than if it were required to build new cars to replace the others. For that purpose it was suggested to my mind that, keying upon the axles a split worm wheel, a motor suspended from the bottom of the car would enable a connection by worm to operate advantageously where the dust could be prevented from entering the worm and where oil could be maintained to lubricate properly the worm and the worm wheel. Therefore, keying upon the axle a split worm wheel bolted together, on the boss or hub of that wheel there was a box supporter which gave the opportunity of giving two journals, one on each side of the worm. Both of the axles so furnished—the worms were made right and left—were reversed, one operating above, the other operating below the axle. This relieved the thrust which would otherwise result, and the friction and loss of power which the wearing on the collar would entail. The difficulty hitherto in placing the motor where it would not be subject to the pounding of the track seemed to be relieved by using a flexible axle. That is, the armature shaft connecting with the shaft of the worm wheel, about seven inches on each side was a spring or double spring, so that the flexibility of that shaft would allow for the difference of the load or from the wearing of the boxes. I had occasion to show the plan at the electrical society some time ago, and I doubt whether I have the power in language to give you a clear description without the drawing. But so far, I have not had the opportunity of placing it upon a car, and although it has excited the favorable comment of those who are expert in such matters; yet no man can promise from an idea, no matter how carefully studied, that which experiment only can prove.

Captain Michaelis leaving in order to catch a train, Mr. Mailloux was called to the chair.

Mr. Mailloux (after thanking the members for calling him to the chair, and stating he doubted whether he could fill the large gap left by the departure of Captain Michaelis), said:—We have with us this evening one of the gentlemen who is interested in financiering in connection with these matters—Mr. Stiles, the treasurer of the Van Depoele company, and I have no doubt he could give us some very interesting details and statistics—tell

Digitized by Google

how much the roads are being run for, and other matters of interest.

Mr. Stiles—I presume that some one was laboring under the impression that I was an electrician, and I beg to assure you that I am not, and I know but little about electricity. Still I think if I could get the worthy president to interpret for me, I might make a tolerably fair speech. I do not think I could say anything that would be of interest to you, in the line that should be discussed here to-night. I simply know that with the Van Depoele company we are operating some six roads every day. Our road is in operation at Scranton and we would be very glad to see any of you there to examine it. I have had great faith in electricity as a motive power, and I have invested considerable money in it: and I have faith in electricians—especially Mr. Van Depoele. As I said before, I know absolutely nothing about electricity and how little I know perhaps I could illustrate by a little anecdote. A young gentleman called on me a short time ago to engage as an electrician. He gave me his card as an electrical engineer. I asked him what he knew about electricity, and he said he knew all about it. Of course that satisfied me as it would anybody that was interested in that business: and I told him that I knew there were electricians and electrical engineers but I had very grave doubts whether there was any such thing as electricity; and he attempted to convince me that there was, but failed and left me in disgust.

Gentlemen, I thank you for the honor conferred upon me in asking me to speak but I really don't think there is anything that I could interest you with.

Mr. Martin—How many miles of track are you running Mr. Stiles?

Mr. Stiles—We were figuring it up the other night, something like 30 miles I believe.

Mr. Martin—Every day?

Mr. Stiles—Every day. We have six roads and what I consider the best part of it is, they are all paid for.

Mr. Martin—How many cars?

Mr. Stiles—About 28 cars. The road that we are not now running at Minneapolis is being run by steam power. The cars were ordinary cars the same as steam cars. We put in electricity as a temporary affair, to enable the company to run their cars until they could get some ordinance to allow them to run by steam. However, they have offered to purchase the apparatus of us, but they have had some misfortunes,—and especially in the soda motor line. They were trying to operate four soda motors made by the Baldwin Locomotive Works. The last time I was there, Mr. Hill, the engineer—there were four boilers built by that gentleman—called my attention to the coal on the floor—about two bushels. He said that was the last of 30 tons they had used to charge that one motor with, and they hadn't got it to run yet. So I concluded that there was something else that they wanted.

Mr. Mitchell—I have heard about some great eastern motor at the Rhode Island Works in Providence. I understand there is a very large motor being built there, and I would be very glad personally to hear about it.

The Chairman—I can state for the information of the gentleman that I was in Providence recently for examination of that particular system, and that at that time the motor was still on paper. It hadn't got any farther. They have a motor which is capable of 50 to 75 h. p. for street traction; but they hadn't yet begun to work on the large electrical motor—that 600,000 Watts motor, I understood you to mean.

The secretary read a communication from Mr. R. M. Hunter, as follows:

Office of
THE HUNTER ELECTRIC RAILWAY CO.,
No 926 Walnut street,
Philadelphia, Dec. 6th, 1886.

RALPH W. POPE, ESQ.,
Sec'y American Institute of Electrical Engineers,

DEAR SIR:—I expect to be present at the meeting Dec. 7th, but should I not find it possible, I would request you to state to the meeting that I find the prejudice against the practicability of electrical propulsion, which was so strong several years ago, fast disappearing, and that it is now the first thought as a possible motive power. My experience, as expert for the National Cable Railway Co., has satisfied me that cable traction is doomed, and that many of the cable railways now in existence will be converted into electric roads. This inclination was in existence even in 1883 when I had a project under consideration to convert the Chicago city railway into an electric railway, and so far back as 1881, I endeavored to induce the Union railway (now the Traction Co.) of Philadelphia, to adopt electricity in place of their cable railway then building on Columbia avenue. The Cable company is inclined now to believe in the change. At the present time the Hunter Electric Railway Co., is estimating for the construction of four roads aggregating nearly 20 miles of track and 110 motors cars, located in Pennsylvania and New Jersey. It is also negotiating for the equipment of a road in Massachusetts and a sub-company for that state, and another in Pennsylvania, aggregating at least 30 miles of track. The prospect for the introduction of electricity for street car propulsion is very flattering.

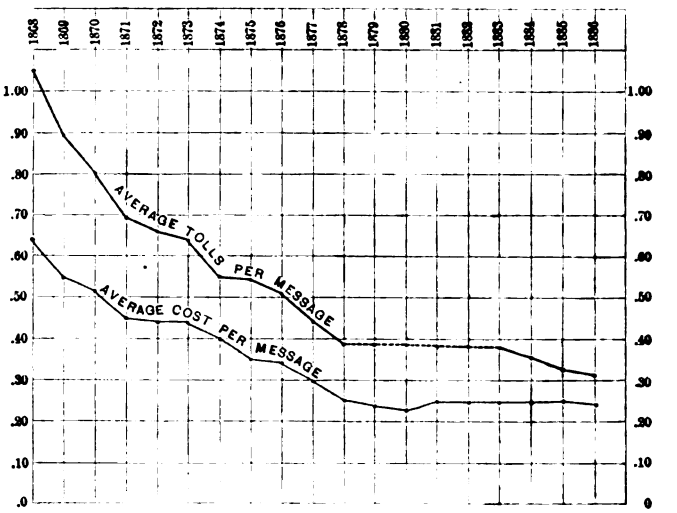
Very truly,
R. M. HUNTER.

The chairman called the attention of members to the fact that some doubt had been expressed of the advisability of continuing meetings so often as once a month. The desire to go on with the monthly meetings appeared to be general among the members present, and on motion it was voted that the consideration of the subject of electric railways be continued at the next monthly meeting. The meeting then adjourned.

The following named gentlemen were present:

Capt. O. E. Michaelis, U. S. A.
R. W. Pope.
C. O. Mailloux.
G. A. Hamilton.
G. M. Phelps, Jr.
Mr. Carey.
J. M. Orford.
J. Murray Mitchell.
Sidney F. Shelbourne.
David E. Lain.
S. D. Field
E. L. French.
Schuyler I. Wheeler.
Edmond Julien.
Baron Edouard de Coters.
Pedro G. Salom.
Henry G. Morris.
Stephen D. Hatch.
Wm. Bracken.
Joseph Wetzler.
Col. Roger Jones, U. S. A.
Dr. A. R. Ledoux.
W. M. Callender.
Mr. Butterworth.
T. C. Martin.
A. A. Knudson.
J. M. Pendleton.
G. W. Mansfield.
C. E. Stump.
C. J. Van Depoele.
Mr. Stiles.

CHART SHOWING AVERAGE TOLLS AND AVERAGE COST PER MESSAGE OF THE WESTERN UNION TELEGRAPH COMPANY FOR TWENTY YEARS.



PATENT OFFICE BUSINESS, 1885-1886.

The President's message says of the United States patent department:

On the fourth of March, 1885, the current business of the patent office was, on an average, five and one-half months in arrears, and, in several divisions, more than twelve months behind. At the close of the last fiscal year such current work was but three months in arrears, and it is asserted and believed that in the next few months the delay in obtaining an examination of an application for a patent will be but nominal.

The number of applications for patents during the last fiscal year, including reissues, designs, trade-marks and labels, equals 40,678, which is considerably in excess of the number received during any preceding year.

The receipts of the patent office during the year aggregate $1,205,167.80, enabling the office to turn into the treasury a surplus revenue, over and above all expenditures, of about $163,710.30

The number of patents granted during the last fiscal year, including reissues, trade-marks, designs and labels, was, 25,619; a number also quite largely in excess of that of any preceding year.

The report of the commissioner shows the office to be in a prosperous condition, and constantly increasing in its business. No increase of force is asked for.

The amount estimated for the fiscal year ending June 30th, 1886, was $890,760. The amount estimated for the year ending June 30th, 1887, was $853,960. The amount estimated for the fiscal year ending June 30th, 1888, is $778,770.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

In compliance with a call issued by chairman A. J. De Camp, the executive committee of the National Electric Light Association met Dec. 21st, at the Hotel Lafayette, Philadelphia, to make arrangements for the third annual meeting of the association.

Digitized by Google

The following gentlemen were present at the meeting; A. J. De Camp, of Philadelphia, chairman; Frank Ridlon, of Boston; Dr. Otto Moses, New York; James T. Lynch, New York; Clarence E. Stump, of the *Electrical World*, New York; Arthur Steuart, Baltimore; George W. Boyer, Philadelphia; Thomas McCoubray, Jr., and J. F. Morrison, of Baltimore.

The convention will be held either in Horticultural Hall or the Union League Annex, Philadelphia, on Tuesday, Feb. 15, next, but the headquarters will be at the Hotel Lafayette. There will be nearly three hundred delegates present, among whom will be Dr. Duncan, Prof. Rowland, Prof Thurston and Prof. Brackett.

The association was organized in Chicago in 1884, and now includes in its membership many leading electricians and the greater portion of the electric light companies in the country.

A feature of the convention will be an exhibit of electrical apparatus by the manufacturers.

THE FRENCH EXHIBITION OF 1889.

Electricity and its applications will be comprised in class 62 in the general classification of the Paris Exhibition of 1889, and will be arranged as follows: 1. The production of electricity; static electricity; batteries and general apparatus. 2. Magneto and dynamo-electrical machines; accumulators; transmission of electricity; cables and other conductors with accessories; lightning conductors; Electrometry; measuring apparatus; electrical counters. 4. Applications of electricity; telegraphy; signals; telephouy; microphony; photophony; the electric light; electric motors; electric locomotion; transmission and distribution of power; transformers. 5. Medical electricity; electro-chemistry. 6. Magnets and electro-magnets; compasses; electric clocks; miscellaneous apparatus. On the 17th of October, M. Lockroy, minister of commerce and industry, nominated a double committee to preside over this class. The first consists of forty members, and comprises such well-known names as Becquerel, Marcel Deprez, Mascart, Carpentier, Fontaine Joubert Lemonnier, Menier, Mercadier, De Meritens, Planté, Richard, Viverez, L. Weiller, etc. The second is composed of 29 members, and includes M. M. Barba, Bourgalt, Debroze, Delaunay, Duval, Farcot, Krebs, Laurens, Richard, Tissandier, etc. The first committee will preside over strictly electrical matters, and the second will take charge of machines and practical applications.

BROOKLYN SUBWAY WIRES.

The Electrical Subway Commission of Brooklyn, in its report to Mayor Whitney, says that the total length of underground conduit finished during the year is 366,000 feet, the maximum capacity of which is estimated at 7,400 miles of wire. Already 1,121 miles of wire have been drawn into the subway, and it will be brought into service as rapidly as possible. Thus far a little more than 82 miles of aerial conductors have been taken down, and the work will be extended as rapidly as possible to all the streets embraced in the proposed plan. The commission declares that the problem appears to be solved, so far as telephone and telegraph lines are concerned. This reference is made to the electric light conductors:

"The board has found no device which would with certainty, in its opinion, enable the wires carrying arc light currents to be safely and successfully operated in the same conduit with telephone and telegraph conductors without disturbance or injury to the latter. Hence the consideration of the arc light conductors must have reference to independent conduits kept at a distance from the telegraph and telephone conduits. It has been a question whether the electric light companies employed to light the streets under contract with the city could be legally obliged to place their wires underground. Recently, in view of the general public interest in the subject, the board obtained through your courtesy the opinion of the corporation counsel, which raises, however, for the consideration of the board, another question, namely, if the city authorities have made contracts at a certain price for lighting the streets, could this board properly impose upon the contractors an underground system which, though technically practicable, was financially impracticable under the terms of the contract. This would certainly bring the board into an undesirable and mischievous attitude of conflict."

Prof. Geo. W. Plympton, president of the commission, lately made an extended tour in Europe, and thus gives the result of his observations:

"The problem of construction of a telephone system on such a scale as exists in American cities with underground wires has not yet been solved abroad. In Europe no attempt has been made to solve it, because as yet there is no such general use of the telephone. The number of telephones in the United Kingdom of Great Britain reported on January last, was 13,000, while in the United States at the same date there were 327,000. There are more telephones in use in New York and Brooklyn than in all Great Britain, more in New York city alone than in all France. For the accomplishment of the ultimate object of converting our overhead electric systems of all kinds to underground systems, without impairing the efficiency of their service, without permanent injury to our streets, and without increasing the cost of the same, we must depend upon the experience gained and experiments made on our own side of the Atlantic."—*N. Y. Sun.*

NEW YORK SUBWAYS.

STATUS OF THE BIG CORPORATIONS IN THE NEW COMPANY.

The reorganization of the Subway Construction Co. is being pushed briskly forward in the interim of idleness, while the Averell company keeps its fires banked in readiness to begin work at the first return of fair weather. At the presentation of the memorial of the commission to ex-president Roswell P. Flower, Mr. Edward Lauterbach declared that over $2,000,000 had been subscribed for further subway work by men who were able to put in 500 times that amount. This was, of course, understood to refer to the Western Union Telegraph Co. and to the Metropolitan Telephone Co., and matters have thus far progressed so satisfactorily that the new board of directors will be announced early next week.

It is understood that the construction company, following out its extensive plans, has contracted for 800 miles of conduits, about 35 miles of linear combined sections; and engineer Kearney is at present preparing the routes to be begun in all directions in the early spring, the big telegraph companies giving the assistance of their engineers in the preparations.

A gentleman well on the inside declared yesterday that there were some peculiar features about the reorganization. "In reality," he said, "there will be little change in the present Construction company, but nevertheless the Western Union and the Metropolitan Telephone interests are being organized as a sort of sub-construction company, and this is the party which has contracted for 800 miles of conduit. In one sense this company is simply the creature and underling of the original Construction company, which is the only one the commission will recognize and which is now practically Mr. Edward Lauterbach. The commission and Mr. Lauterbach will still be the prime movers in the selection of routes and materials, but the 'suggestions' of this sub-company will really be carried out. The Western Union and the Metropolitan Telephone Co. will bear the expense of the construction of the conduits, and will receive in payment therefor the bonds of the Construction company."

"But where are the electric light and the smaller telegraph companies to come in?" asked the reporter.

"That is amply provided for," was the reply. "The Construction company declares that it will hold the majority of stock and that the Western Union and the Metropolitan Telephone companies will only be permitted to secure a minority. The conduits will be built of sufficient capacity for all, and the smaller companies will have an opportunity to come in according to their needs. It is only right that the routes desired by the big companies should be completed first, as they will require a majority of ducts, but we are confident that everything will work smoothly and nobody will be crowded out.—*N. Y. Sun.*

FUEL AND LIGHT.

Of the Westinghouse plan for furnishing fuel gas and electric light in union, the following points may be said to be accomplished towards the success of the scheme: 1. A system of appliances has been successfully developed for the distribution and use of gas fuel in Pittsburg and other cities in the natural gas region, and these features are no longer experimental. 2. The desirability and popularity of gas as fuel has also been proved in the same cities. 3 Electricity for operating 1,000 lamps of 100 volts each has been transmitted over No 5 copper wire to a point three miles distant, and the above number of lamps have been operated from that distance from the dynamo. It yet remains to produce and accumulate, under pressure, a water gas or other proper gas for fuel, and this is something that should be easy of accomplishment.—*Light, Heat and Power.*

ELECTRIC LIGHT AND POWER.

Domestic.

An electric light company has been organized at Greenfield, Mass., with these officers: President, J. H. Sanderson; secretary and treasurer, F. H. Hardison; directors, L. J. Gunn, N. S. Cutler, J. H. Sanderson, J. W. Stevens, S. E. Wells. The capital is to be $10,000, and has nearly all been subscribed. Nothing has yet been done toward locating the plant or deciding what system is to be adopted, but the directors will begin their work at once.

The Belvidere Gas and Electric Light Co., Belvidere, N. J, has been incorporated. Capital stock $30,000. Edward M. Beesley, and others, incorporators.

The West Troy and Green Island Electric Light Co., limited, West Troy, N. Y., has been incorporated. Capital stock, $50,000. Thomas Knowlson, and others, incorporators.

The Canton Schuyler Electric Light Co., Canton, Ohio, has

Digitized by Google

been incorporated. Capital stock $50,000. James H. McLain, and others, incorporators.

A company is being organized at Hyde Park, Mass., to be known as the Hyde Park Electric Light and Power Co. Robert and John S. Bleakie, and others, are interested.

The Morristown Electric Light, Heat and Power Co., Morristown, N. J., has been incorporated. Capital stock, $50,000. Henry W. Pope, and others, incorporators.

The Westinghouse Electric Light, Heat and Power Co., Elizabeth, N. J., has been incorporated. Capital stock, $100,000. Henry W. Pope, and others, incorporators.

Franklin, Pa., will be lighted by electricity. F. W. Mitchell and D. C. Grant are interested.

St. Albans, Vt., will be lighted by electricity. W. T. Smith, and others, are interested.

South Framingham will be lighted by electricity. For further particulars address Willis M. Ranney, South Framingham, Mass., or S. O. Daniels, Natick, Mass.

The Electric Light and Power Co., Steubenville, Ohio, has been incorporated. Capital stock, $50,000. Charles H. Steele, and others, incorporators.

A system of electric lights will be put up in Naugatuck, Conn. For further information, address A. H. Dayton.

The Westboro Electric Light and Power Co., Portland, Me., has been incorporated. Capital stock, $25,000. President, Christopher Whitney, Westboro, Mass.

Nevada, Mo., will be lighted by electricity. John Martin can furnish particulars.

The Thomson-Houston Co. has been awarded the contract for lighting the city of Fulton, N. Y., with electricity.

The Putnam Electric Light Co., Putnam, Conn., has been incorporated. Capital stock, $12,000. Gardner L. Miller, and others, incorporators.

The Northampton Electric Light Co., Northampton, Mass., has been incorporated. Capital stock, $40,000. E. P. Copeland, and others, incorporators.

The Wellsboro Light and Heat Co., Wellsboro, Pa., has been incorporated. Capital stock, $10,000. Treasurer, J. L. Robinson.

The Clinton Gas Light Co., of Clinton, Mass., has filed a petition for permission to increase its capital to $250,000. It also desires to have its charter so amended as to enable it to furnish electric light and power to Clinton and Lancaster.

New England towns are taking a strong lead in illuminating with electricity. Biddeford, Me., has just put in a 100-light plant of the American system.

The Norwich Gas Light Co., Norwich, Conn., has purchased a controlling interest in the local electric lighting company.

The authorities of the torpedo station, Newport, R. I., are considering the matter of putting in a system of electric lighting for all the buildings.

The Union Steel Co., of Chicago, are now adding a 60-light Brush machine to their electric lighting outfit. They have for some time been using 70 lamps and two dynamos.

Foreign.

England.—Some engineers still speak of electric lighting as untrustworthy. One railway engineer recently refused to light an underground railway by this light, chiefly because of its uncertainty, but another railway engineer is not only lighting Paddington station, one of the largest in London, but he is lighting all the signals by the same means, the strongest possible proof of the reliance some men put in electric lighting, and this even with an alternating current. An underground line is just the place where gas should not be used, but the engineer of the Mersey line laid great stress on the higher cost of the electric light. When railway signals are properly lighted by electricity they may be also worked by the same means.

The London, Brighton, and South Coast Railway Co. have given an order to the Railway Electrical Contractors (limited) for a considerable extension of the system of lighting railway carriages by electricity, which has been successfully in operation on the above line for some years past.

Holland.—Negotiations are in progress between the Dutch company which holds the concession for lighting the Hague with 13,000 incandescent and arc lamps and certain leading Berlin firms for the formation of a company to undertake the electric lighting of Dutch towns in general. It is proposed to name the new company "The Netherlands Electrical and Metallurgical Company."

PERSONAL MENTION.

Messrs. Price & Steuart, counsellors and attorneys at law, Baltimore, announce their purpose to add to their practice in the courts in patent and trade-mark cases the work of soliciting American and foreign patents and trade marks.

MANUFACTURING AND TRADE NOTES.

Mr. Benjamin Blum, formerly of J. H. Bunnell & Co., and Mr. Benjamin Sturges, late secretary of the Manhattan Electric Co., have formed a partnership under the firm name of Sturges & Blum. They propose to do a general electrical business, making a specialty of putting in electric bells, burglar alarms, etc.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER, *by* Pope & Edgecomb, *Solicitors of Patents for Electrical Inventions, 11 Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From November 23d to December 14th, 1886 (inclusive).

Alarms and Signals:—*Automatic Electrical Signal-Coupler*, J. S. Copers, 352,990. *Thermostat*, G. Westinghouse, Jr., 353,186, November 23; R. L. Gulon, 354,131, December 14. *Window-Spring for Electric Burglar Alarms*, T. H. Parker and J. Geary, 353,269. *Striker for Electric Bells*, C. A. Tucker and W. H. Markland, 353,273. *Electric Bell*, C. A. Tucker and O. H. Huebel, 353,274, November 23. *Fire Alarm Signal Box*, J. Ashworth, 353,475, November 30. *Electric Annunciator*, G. E. Painter, 354,209. *Electrical Number Indicator*, W. J. Cull and C. F. Scattergood, 354,505. *Indicator for Reservoirs*, S. Fraleigh, 354,508, December 14.

Clocks:—*Electric Clock for Transmitting Signals*, J. S. Bailey, 353,840, December 7. *Circuit-Breaker for Electric Clocks*, V. Himmer, 354,525, December 14.

Conductors, Insulators, Supports and Systems:—*Insulator*, R. G. Brown, 353,120, November 23. *Composition of Matter for Insulating Electric Conductors*, C. J. Van Depoele, 353,653. *Angle-Hanger for Acoustic or Mechanical Telephones*, M. Gerst, 353,489, November 30. *Conductor for Mechanical Telephones*, J. S. Jones, 353,683 and 353,684, December 7. *Distributing Appliance for Electric Lighting Systems*, E. W. Rice, Jr., 354,233. *Apparatus for Electrical Distribution*, M. M. M. Slattery, 354,258. *Apparatus for the Distribution of Electricity by Means of Secondary Batteries*, E. Thomson, 354,272. *Underground Electrical Conduit*, B. Williams, 354,290. *Insulating Joint*, D. Williamson, 354,291. *Electrical Conductor*, E. H. Johnson, 354,320. *Conduit, for Cable or Electrical Railways*, E. Samuel, 354,350, December 14.

Dynamos and Motors:—*Dynamo-Electric Machine*, R. M. Mather, 353,151, November 23; N. S. Keith, 353,310; C. Coerper, 353,414, November 30. *Brush-Holder for Dynamo-Electric Machines*, A. Schmid, 353,164. *Regulator for Dynamo-Electric Machines, Motors, &c.*, E. Thomson, 353,180. *Regulator for Electric Currents*, same, 353,179, November 23. *Regulator for Dynamo-Electric Machines*, E. A. Sperry, 353,986, and 353,988. *Electric Regulator*, same, 353,990. *Annular Armature for Dynamo-Electric Machines*, same, 353,989, December 7. *Regulator for Dynamo-Electric Machines*, E. Thomson, 354,273. *Armature for Dynamo-Electric Machines*, D. Williamson, 354,292, December 14. *Mode of Connecting and Disconnecting Generators for Electric Lighting*, J. W. Howell, 353,035, November 23. *Automatic Circuit-Controller for Electro-Plating Machines*, C. J. Van Depoele, 353,334, November 30. *Electric Motor for Sewing Machines*, E. Recordon, 353,003, November 23. *Electric Motor*, E. A. Sperry, 353,987, December 7; N. H. Edgerton, 354,111, December 14. *Governor for Electric Motors*, A. W. Meston, 353,367, November 30.

Galvanic Batteries:—*Electric Battery*, J. A. Kendall, 353,141, November 23. *Voltaic Battery*, A. F. W. Partz, 353,757, December 7. *Primary Galvanic Battery*, C. E. O'Keenan, 354,434, December 14.

Ignition:—*Dynamo-Electric Igniting Machine*, J. H. Smith, 353,827, Dec. 7.

Lamps and Appurtenances:—*Incandescent Electric Lamp*, A. L. Reinmann, 353,158, November 23; C. J. Van Depoele, 353,333, November 30; T. A. Edison, 353,783, December 7. *Electric Arc Light*, G. C. Pyle, 353,643, November 30. *Application of Secondary Batteries to Electric Lighting*, E. R. Knowles, 353,142, November 23. *Regulator for Electric Arc Lamp*, H. Henneberg and R. O. Lorenz, 353,305, November 30. *Manufacture of Carbon Conductors*, T. A. Edison, 354,310, December 14.

Miscellaneous:—*Electric Elevator*, J. H. Clark, 353,128. *Electric Switch Board*, J. W. Wehrle, 353,184. *Electric Door Opener*, A. Lungen, 353,263, November 23. *Electric Therapeutic Instrument*, C. E. Baldwin, 353,346. *Electrical Appliance for Dental Chairs*, L. J. Deckard, 353,403. *Electric Circuit Controller*, W. Stanley, Jr., 353,603. *Carbon for Electrical Purposes*, E. Shaw, 353,598. *Electrical Apparatus for Working Valves*, H. Likly, C. A. Carpenter and F. B. Graves, 353,637. *Electric Current Indicator*, M. Waddell, 353,649, November 30. *Electrical Testing*, C. S. Bradley, 353,915. *Automatic Fire-Extinguishing Apparatus*, A. Thompson and R. O. Ritchie, 353,766. *Coupling for Electrical Conductors*, W. F. Smith, 353,984, December 7. *Resistance Block for Electric Circuits*, M. M. M. Slattery, 354,257. *Induction Coil*, E. Thomson, 354,274. *Electric Cut-Out*, C. Eschwei, 354,466, December 14.

Railways and Appliances:—*Electric Locomotive*, C. J. Van Depoele, 353,335, November 30. *Electrical Propulsion of Vehicles*, F. J. Sprague, 353,829. *Electro-Magnetic Car-Brake*, H. S. Park, 353,880, December 7. *Alarm for Railway Trains*, G. E. Carpenter and A. F. Tucker, 354,302. *Railway Signal*, T. D. Williams and G. M. Eitemiller, 353,393, November 30; G. D. Burton, 354,460, December 14. *Railway Telegraph*, E. B. Ives, 353,789, December 7. *Electric Lighting of Railway Trains*, C. E. Buell, 353,248, November 23 and 353,349, November 30. *System of Lighting Cars by Electricity*, J. H. Marshall, 353,797, December 7.

Secondary Batteries:—*Secondary Battery Element*, C. Sorley, 353,511, November 30. *Secondary Battery*, V. Sass and K. Friederich, 354,352, December 14.

Telegraphs:—*Multiple Telegraphy*, S. D. Field, 353,128, November 23. *Autographic Telegraph*, J. H. Robertson, 353,592, 353,593 and 353,594, November 30. *Printing Telegraph Instrument*, A. Wirsching, 354,001, December 7. *Electro-Phonetic Telegraph Sounder*, H. A. House and H. A. House, Jr., 354,139, December 14. *Electric Telegraph*, E. A. Comper, 353,541. *Electric Telegraph Relay*, J. I. Conklin, Jr., 353,288, November 30. *Telegraph Transmitter*, J. W. Shryock, 353,715, December 7.

Telephones, Systems and Apparatus:—*Telephone Transmitter*, W. Burnley, 353,536, November 30; J. W. McDonough, 353,694, December 7; A. W. Rose, 354,241, December 14. *Telephone Receiver*, J. C. Eichmeyer, 354,402, December 14. *Microphone*, T. Wallace and O. A. En Holm, 353,337, November 30. *Telephone*, N. F. Palmer, 353,755, December 7; W. J. Morton, 354,169, December 14. *Individual Call Apparatus*, L. S. Glover, 352,948, November 23. *Switching Apparatus and Test Circuit for Telephone Exchanges*, J. J. Carty, 353,350, November 30. *Telephone Apparatus for Divers*, H. V. Hayes, 353,940, December 7. *Adjustable Support for Telephones*, C. C. Gould, 354,469 December 14.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

NEW YORK, FEBRUARY, 1887.

ANNOUNCEMENT TO SUBSCRIBERS.

WE are pleased to recognize the fact that a principal source of the growth of our subscription list is the favorable commendation of the ELECTRICIAN AND ELECTRICAL ENGINEER by those who are already subscribers, to their friends and acquaintances

We shall continue our endeavors to deserve your appreciation and good-will, by keeping up, and if possible improving the quality of our paper. To any of our present readers who may find it in their way to increase our list, we offer rates for 1887 as follows:

For your own subscription	and	1	new name	.....		$5 00
" " "	"	2	"	.....		7 00
" " "	"	3	"	.....		9 00
" " "	"	4	"	.....		10 00

This offer will hold good until April 1st.

The *Telegraphic Journal and Electrical Review*, London, will be supplied for one year in conjunction with the ELECTRICIAN AND ELECTRICAL ENGINEER for the additional sum of $4.00 with any subscription.

In addition to the usual methods prescribed for making remittances, money orders issued by the American, United States or Wells Fargo express companies will be found safe, cheap, and convenient.

Very respectfully yours,

ELECTRICAL PUBLISHING CO.,
115 Nassau St., New York.

THE FIRE RISK IN ELECTRIC LIGHTING.

TWO recent fires, one destroying the Temple Theatre at Philadelphia, the other causing considerable damage to the building occupied in part by the central staiton of the Rhode Island Electric Light Co. at Providence, have drawn general attention again to the question of the danger of fire from electric lighting. It has afforded a theme for letters and editorials in the daily press, of varying degrees of accuracy as to facts and deductions from them.

Loss of life at the Philadelphia fire necessitated a coroner's inquest. The theatre was lighted by incandescent lamps of the Edison company's system. The verdict rendered included the following finding on the origin of the fire "We find that there was no evidence of other cause of fire save electricity; that the fire was not due to incendiarism; that without proper workmanship, care and conditions, it is possible to cause fire by means of incandescent light currents of low potentiality in many ways." The jury appended to its finding an expression of its "obligations to inspector McDevitt, of the insurance patrol, for his skillful experiments, proving conclusively—*First:* that incandescent lamps will set fire to inflammable substances when the heat in them is confined and allowed to accumulate, and that the lamps need not break in order to do this; *Second:* that the breaking of an incandescent lamp will set fire to inflammable gases; *Third:* that the breaking of an incandescent lamp does not ordinarily set fire to solids, even if quite inflammable; *Fourth:* that water or moistened wood will short-circuit incandescent circuits and cause fire in so doing; *Fifth:* that loose joints, unsoldered, are dangerous and liable to cause fire; *Sixth:* that the wearing away of insulation on flexible leaders will cause fire unless safety plugs are used; *Seventh:* that a careful system of safety plugs for all parts of a circuit, thorough insulation for all parts of a circuit, soldered joints, and care not to place lamps so that heat can accumulate, are first requisites in a safe system of incandescent lighting." The jury also found "that the wiring adjacent to inflammable canvas and curtains in the Temple theatre was found to be so imperfectly done as to be dangerous. The origin of the fire in the Musee department of the theatre was the incandescent light current. While we think it our duty to state the possible causes of fire by means of electric light circuits, we believe the risk to be controllable, and a minimum in case of workmanship by reliable companies."

We believe that the destruction of the Temple theatre is the first case of a disastrous fire of which the origin has been traced to an electric light circuit. The fires hitherto attributable to this cause have been comparatively trifling, having for the most part been promptly discovered and extinguished before much damage ensued.

In view of the facts developed by the testimony in the coroner's inquest, the assignment of the electric light circuit as the cause of the Philadelphia Temple theatre fire seems reasonable enough. The fire started in a booth about eight by twelve feet in size, with canvas partitions, lighted by an incandescent lamp, hung by a flexible conductor. Wm. F. Connor, the electrician of the theatre, testified that the flexible conductor was in contact with the drapery of the booth. Specimens of the electric light wires, taken

Digitized by Google

from the circuit near the lower tier of booths, were shown; the twisted and unsoldered joints of which were declared by Mr. Johnson, president of the Edison company, to be examples of defective and dangerous work of the worst sort.

The examination, before the jury, of electrician Connors indicated very clearly that the wiring of the building had been largely intrusted to incompetent hands. He admitted that he did not know what the real condition of the wire joints was. He also testified that the lamp in the booth was hung within eight inches of a rolling curtain. The experiments of Inspector McDevitt, illustrating the dangers of too small conductors, of inadequate insulation, of placing wires in close proximity to each other on supports subject to gathering moisture, of the ignition of inflammable gases by the bursting of lamp globes, and finally showing the possibility of burning a cloth wrapped around and enclosing a lamp globe, will not surprise instructed electricians. The last contingency of the above series is one which has probably received much less attention from electric light men than any of the others. It has naturally been regarded as very remote, and it is so in fact. That the little heat radiated from an electric light bulb will, if closely confined and permitted to accumulate for a sufficient time, ignite a combustible fabric, is not to be doubted. Practically, however, such a condition could hardly arise without deliberate preparation or the grossest carelessness. If a man will hang his overcoat upon an incandescent lamp, he need not be surprised to find a hole scorched through it.

The precise manner in which the fire at the theatre was started by the electric light circuit has not been ascertained. That it was due to a defect in the wiring or flexible conductor in the booth, seems more probable than that it arose from confining the heat of the lamp.

The investigation of the circumstances of the fire at the electric light station at Providence, has shown quite conclusively that it was caused by an explosion of gas, generated by the burning of soft coal under the boilers. A thorough expert inspection of the electric light machinery and of the wiring in the building, disclosed no defect, nor any indication that they had any part in causing the fire. The nature and location of the damage were precisely such as would arise from an explosion of a light gas; the damage was found upon or near the ceilings; very combustible materials near the floors were unharmed. The situation of the boiler room, its opening into the ground floor of the building, the openings through the floors from story to story, the use of soft coal, begun the night before the fire, the probability that the fire had been banked a short time before the fire occurred, and finally, the terrible burning of fireman O'Brien, in connection with his words "it was the boilers," are circumstances that permit no doubt as to the origin of the fire. Electric lighting may be conceded as absolved from any responsibility for the Providence fire.

Not so, however, as to the Philadelphia fire. Yet, it is undoubtedly true that electric lighting is far safer than any other mode of illumination. Like other good causes it sometimes suffers at the hands of its injudicious friends. It has been a mistake of some advocate to assert the entire absence of fire risk in electric lighting *per se*. It has been the mistake of some constructors of electric light plants to act, apparently, as if this were true, and to disregard, as to plans, materials, and workmanship, the precautions which will practically nullify the elements of danger. The frank language of president Johnson, of the Edison company, on this point, before the coroner's jury at Philadelphia, is to be commended.

It is fully within the knowledge of insurance managers as well as of electricians, that, while the large quantity of physical energy employed in an electric light plant is capable of inflicting damage or destruction upon both life and property, the methods and means of absolutely controlling it, confining it to its proper channels and work, are definitely ascertained and capable of application in all cases; that the flow of the electric current may be, and is, made as harmless as the flow of water, through houses and streets. A chief point in the superior safety of electric lighting lies in the fact that, unlike gas, oil or other illuminants, it does not supply the material of combustion, or fuel for a fire.

The clear lesson from the Philadelphia fire is that both constructors and purchasers of electric lighting outfits must see to it that every part of the work be intrusted to competent hands, that in plan, material, and execution, it be up to the level of the present well-known and simple provisions for safety.

THE DEATH OF THREE PROMINENT MEN.

Professor Edward L. Youmans died, at his residence in this city, January 18th, at the untimely age of 65 years. Few men, if any, have done so much as he for the popularization of scientific knowledge and literature in this country, or, indeed, in all English-speaking countries.

Born at Coeymans, N. Y., on the banks of the Hudson, June 3, 1821, he removed with his parents, while still a child, to Saratoga. At the age of thirteen he was attacked by a disease of the eyes, and was totally blind for several years. He manifested at an early period the fondness for chemistry and physics, which gave direction to the pursuits of his whole life. During the period of his blindness he was able to go on with his studies through the devoted assistance of his sister, Anne Eliza Youmans, who read and experimented for him. He contrived for himself a machine with which he did his writing. He never fully recovered the use of his eyes, and, throughout his life, was often unable to read. For about forty years, Prof. Youmans was associated with enterprises of the Appletons' publishing house. While visiting their bookstore, forty years ago, whither he had been led by his sister in pursuit of scientific books, he entered into conversation with W. H. Appleton, who was quickly interested in him. As a result, his widely-known "Class-Book of Chemistry" was published by the Appletons in 1852.

Prof. Youmans placed a lasting obligation upon the reading public in 1864, by the publication of his book on the "Correlation of Forces"—a compilation, with an introduction—which placed within the grasp of the general reader the generalizations of science upon the various forms of energy, and their relations to each other. Doubtless, many of our readers will recall the effect of this book upon their minds, as presenting a conception of the unity of

Digitized by Google

physical research, with the bonds of correlation and equivalence that underlie all manifestations of energy. Prof. Youmans further popularized the doctrines of the conservation of energy and the correlation of forces by extensive lecturing. Two notable lectures were on the "Chemistry of the Sunbeam" and the "Dynamics of Life."

In 1871 he planned the International Scientific Series, to be published in New York, London, Paris, and Leipsic, the arrangement being afterward extended to St. Petersburg and Milan. The project was based on the idea of paying authors from the sales in all countries. Up to the present time 57 volumes of the series have been issued. In 1872 he established the *Popular Science Monthly*.

Prof. Youmans graduated in medicine at the University of Vermont, but never entered practice as a physician. He derived his title of Professor from having accepted the Chair of Chemistry in Antioch College in 1866.

Prof. Youmans maintained an intimate friendship with Herbert Spencer, and Profs. Huxley and Tyndall, whose works he has done so much to make popular in this country. He remained till the end of his life the adviser of the Appletons in matters relating to their scientific publications. All lovers of science, and friends of popular education in clear and accurate knowledge of the world of nature, have reason to lament the loss of one so conspicuously and efficiently devoted to those ends as Prof. Youmans.

* * *

It is safe to say that no American manufacturer has been brought more prominently into public notice for some years past than Mr. John Roach, the veteran shipbuilder, who breathed his last on the 10th of January, in this city. Mr. Roach was born in Ireland in 1813. He came to America at the age of sixteen. He earned his first dollar in a brick-yard in New Jersey; from which humble start, his thrift, energy, and force of character brought him, after years of toil, into the foremost ranks of manufacturers, and made him the leading shipbuilder of America. Having early learned the trade of an iron-founder, he accumulated savings enough to start a small foundry, employing four men at first. This foundry proved the nucleus around which he built up his complete works for building marine engines and iron ships. As a shipbuilder he took and kept the lead. He did not achieve his success without encountering much of difficulty and disappointment, against which he measured his energy and perseverance with undaunted courage at all times.

Mr. Roach acquired the hearty good-will of his employés through his justness and kindness to them, and won a position of high esteem in the business world by his ability and integrity.

* * *

Gen. William B. Hazen, Chief Signal Officer U. S. A., died at his home in Washington, January 16th. Since 1855, when he graduated at West Point, Gen. Hazen had been in the military service. In common with most army officers, he passed several years in frontier service. Disabled by wounds in Texas, he obtained leave of absence in 1859. In February, 1861, he returned to duty, being appointed Assistant Instructor in Infantry Tactics at West Point. In October of the same year, he entered active service as Colonel of the Forty-first Ohio Volunteers. He continued in service to the end of the war of the rebellion, rising to the rank of Major-General of Volunteers, and Brevet Major-General U. S. A. Soon after the close of the war, he was commissioned Colonel of Infantry in the regular army. Till his appointment to the Signal Office in 1880, with the rank of Brigadier-General, his time was spent in a variety of military duties, at home and abroad, during which he found opportunity to develop a talent for authorship, writing and publishing books on the "School and Army in France and Germany," and the "Barren Lands in the Interior of the United States."

The inclusion of the Weather Bureau in the department of the Chief Signal Officer, involving the operation of telegraph lines, brought Gen. Hazen into close relations with telegraphers and electricians. His administration of the Signal Office was characterized by the activity and aggressiveness native to his temperament. He kept up and advanced the range and efficiency of the service. Gen. Hazen will be greatly missed in social circles in Washington, where he enjoyed much consideration.

FARRAGO.

A FRENCH JOKE.

L'Ingenieur Électricien of December 23 thus discourses:

"A fondness for neologism sometimes impels one to the ludicrous. *The Electrician* of London, in an article on Arago, after stating that France claims for him a large part in the discovery of the principles upon which the idea of the telegraph was shown to be practicable, and after being constrained to say, in justice, that this claim is somewhat doubtful, desires fully to concede that Arago's name is properly connected with our experimental knowledge of the induction phenomena associated with the name of Foucault, of which the explanation was afterwards given by Faraday.

"It, therefore, deigns to accord to us that Arago has probably a right to priority in the discovery of the phenomena of induction; but, as the English journal finds the claims of Faraday as valid as those of Arago for giving his name to the phenomena called Foucault currents, it proposes the suppression of Foucault and—new Solomon—to cut in two the names of the English and French physicists, and, in all seriousness, suggests the fantastic name of Farrago, which has set all France to laughing. Farrago is a word implying absurdity, being a synonym for mass or mess, for a medley of confused, disparate things, a boiled dinner, balderdash. Farrago to represent Faraday and Arago! If the inventor of the brilliant idea of coining Farrago ever learns that the physicist Lette had determined the laws of resistance at the same time as Ohm, doubtless the philological English *Electrician* will be willing that Ohm's law shall thenceforth be called the law of Ohmlette! Ohmlette, Farrago, pile it on.

'Risum teneatis Amici.'"

Shall we laugh less, or more, on referring to the article referred to in the *Electrician* (Dec. 17), and finding that the suggestion of "Farrago" was merely a piece of English "chaff," and that the "avec un sérieux dogmatique" was all on the part of our French contemporary?

People interested in various schemes for underground lines in New York, may take heart from Judge Van Hoesen's decision against the application of the Subway Commission to enjoin the New York Underground Telegraph Company.

In our note at foot of page 3, January number, we seem to have been afflicted with a momentary attack of *aphasia* in writing "Prof. Thurston" for *Prof. Houston*, who, as our readers know, was the Electrician of the Philadelphia Electrical Exhibition of 1884. The error was ours, and not Mr. Hering's.

THE ELECTRICAL EXHIBITION AND PURE RESEARCH.[1]

BY M. B. SNYDER,

Professor of Astronomy, Central High School, Philadelphia.

WHEN requested to develop before the Institute, some topic relative to the late electrical exhibition, it occurred to me that there was at least one line of reflection it were well to insist on, before the memory of that brilliant display should fade too deeply. There were those who had reported upon the uses and peculiarities of the special exhibits. There had been full account taken, as well, of the praiseworthy inventive and mechanical skill displayed, as of the immediate practical bearing of the several inventions. There had even been attempted practical tests which should haply add to the commercial recognition and credit of the inventor.

But what should be said if, in our exhibition, we failed to recognize anything more than the genius which presides over mechanisms and patented devices; if, through thoughtlessness or neglect, we ignored that great body of unregistered exhibitors who, by their researches alone, had given silent though effective tribute. It seemed to me that even America, with all its worship of the immediately practical, and with all its bold faith in hap-hazard progress, could well afford, as for a moment it cast a last look upon its first great electro-technical exhibition, to do homage to those far-seeing minds, who in this field had made invention possible and progress a necessity.

I propose, then, that the thread of our reflections shall be the dependence of the electrical exhibition upon pure research. And to prevent misapprehension, I desire that the words "pure research" should be understood to imply that class of scientific work which means investigation for the sake of the beauty of truth and fact, though the applications and the mercenary rewards be never so remote; that holds the advancement of the borders of knowledge under the impulse of an unmeasured faith in the eventual advantage to be its highest, noblest aim. It should, however, not be inferred that antagonism to the so-called "practical science" is intended, except in so far as that name is a cloak for empiricism. Indeed, it would be folly at this stage in the history of any science to moot a distinction between the workers in theory and the workers in application, seeing that it is now well understood that the very highest efforts in each field are only attainable by a just recognition of the claims of the other. We know well that one theory may comprehend a thousand applications, and that one appliance may demand a score of theories. Research and practical application are infinite debtors, the one to the other. And yet the habitual neglect of the claims of the former in our new civilization, is sufficient reason for limiting our attention to research as having so richly contributed to our present practice in electricity.

In addition, however, to the motives already indicated, I should mention at least two others as urging to this line of thought. The first is: The blank discouragement and almost insuperable difficulties encountered by the American student, who may aim to further research for its own sake; the second: the pressing necessity for establishing in our midst foundations whose chief aim shall be the advancement of physical research, and the indoctrination of its results into the public mind. To these points I shall now and again refer.

For, if we could show but a little more clearly how the great practical operations exhibited are the direct result of the past study of experimental and theoretical science; if we could show that all the great inventions presented to our view drew their very existence from the patient and faithful investigations of men engaged in pure research, might we not entertain the fond hope that some more decided, some more earnest movement should be initiated to further that scientific spirit in our midst?

It would be useless to disguise the difficulty of making a statement of this dependence of the exhibited results upon pure science, that should deeply affect every mind. To the majority of spectators at the exhibition, I have no doubt that the prominent impression was the beautiful spectacle realized by the inventors' skill. At most, the immediate practical result was all this type of mind cared to appreciate. They may have been dazed and somewhat puzzled, but it is to be feared that to them the presence of the real presiding genius was never clearly disclosed. There are, however, others who glance through the great display with different eyes. To these are present the long array of experiments and theoretical investigations at the basis of many a single practical result. And again, they recall a single experiment which means ten thousand dynamos of a hundred different types. Let us, then, join this group as it studies the exhibition, and gather at least a few glimpses of the real origin of the important industrial display.

Our attention, as we enter, is for a moment arrested by the title: "The *International* Electrical Exhibition of the Franklin Institute." Now, the warmest admirers of the exhibition admit that there was comparatively little in the way of foreign exhibits to warrant the title international. The quick succession in which such exhibitions had been held in Europe, and the consequent multiplied expense to exhibitors, was undoubtedly the factor which prevented the full realization of the plan of the Institute. And yet, from a philosophical standpoint, the exhibition could not be less than international. We shall, indeed, have to say that nearly all the great spirits in physical research, to whom we have to refer as contributors to the result, were nurtured by the European nations; and that it is to the enlightened encouragement of research abroad that this exhibition owes most.

As we now glance over the character of the electrical display, and note the deftness with which this strange form of energy serves the purposes of our modern life—as we find electricity no more a mere plaything in the hands of a few scientists, but now the willing servant to a thousand-and-one earnest uses, we cannot but mark the severe contrast between this result and the unpromising beginnings.

Instinctively, our imagination turns back to that early American time when, in or near the self-same locality, there was to have been held another electrical exhibition. Strangely enough, we call this the electrical exhibition of the Franklin Institute, while the other was an exhibition given by Benjamin Franklin himself. The marvelous demonstrations in electricity made at that exhibition must indeed have stirred the reflective minds of early Philadelphia as deeply as the wonders of our exhibition could have affected any of us.

It seems that, in a mild spirit of revenge upon the great difficulties encountered in developing anything of immediate use from his electrical experiments, and as a sort of semi-ludicrous, semi-earnest challenge to those who doubted the eventual utility of such high scientific pastimes, Franklin wrote of that earliest American electrical exhibition the following prospectus, which I shall reproduce with his own emphasis:

"Chagrined a little that we have been hitherto able to produce nothing in this way of use to mankind; and the hot weather coming on, when electrical experiments are not so agreeable, it is proposed to put an end to them for this season, somewhat humorously, in a party of pleasure on the banks of *Schuylkill*. Spirits, at the same time, are to be fired by a spark sent from side to side through the river, without any other conductor than the water; an experiment which we some time since performed, to the amazement of many. A turkey is to be killed for our dinner by the *electrical shock*, and roasted by the *electrical jack*, before a fire kindled by the *electrified bottle*: when the

1. A lecture delivered before the Franklin Institute, February 8, 1886.

Digitized by Google

healths of all the famous electricians in England, Holland, France, and Germany, are to be drank in *electrified bumpers*, under the discharge of guns from the *electrical battery*."

We are happy to say that Franklin's dream of something "of use to mankind" from electrical research was fully realized at the recent exhibition, held but a little more than a century after that of his own.

What a glowing picture should we have had from the ready pen of the old statesman, could he, by some magic of the imagination, have been invited into the ideal studio of our modern exhibiting electrician. There he should have found an apartment decorated on every hand with the beautiful results of the electro-metallurgic art, furnished with tables bearing a wealth of electro-plate, with books, fine pictures, and rare scientific drawings, reproduced from electrotypes, with clocks strangely moved and controlled by electricity, with electro-chronographs recording, to the utmost fraction, the time of occurrences a hundred miles distant, with electric signal-buttons ready to register both an audible and visible signal at points near or remote, with telephones that allow a conversation to be held at a distance of twenty miles as easily as with one's neighbor, with telegraphic sounders whose brazen hearts thump with messages that have traveled a thousand miles, with a mirror galvanometer whose delicate indications reveal thoughts that have held their tireless course through 3,000 miles of ocean cable, with sphygmographs that record the frequency and the varying force of the pulse of the sick; with stock tickers telling the continuous story of the rise and fall in the pulse of the commercial world; with signaling devices that make police and fire departments, as well as a host of messengers, our house-servants; with electric lamps shedding the soft radiance of daylight, and serving a score of uses, both useful and artistic; and finally, with electric motors ready to move all sorts of machinery, or, if we choose to use the studio as a traveling car, to speedily propel us from town to town by means of the mystical energy that may pass through a simple wire. All this and much more would have contributed to the contrast of the two periods of early experiment and later use.

If we should only regard the visible results, we might, perhaps, consider the lightning rods attached to our exhibition building as the only remaining indication of the early activity of Franklin and Kinnersley. But we must here insist on a deeper insight into the relations of effect with cause in electrical history. Franklin's chief glory consists in the fact that he was among the first to propound an explanation of electrical action; to clearly moot a theory which should thenceforth be used for the furtherance of experiment. If he was among the first to show, experimentally, "the wonderful effects of pointed bodies, both in *drawing off* and throwing off the electrical fire," he was also among the first to take a broad survey of the whole problem of loss of electrical charge, and, above all, to propose to himself such a conception of the action of the "electrical fire" as should be applicable to every form of experiment.

All the way from the sixth century B. C., when Thales rubbed the *elektron*, and noted its attractive effect on light bodies, down to the middle of the eighteenth century, when Franklin and Symmer first stirred the scientific world by their theories of electricity, we note only, for the most part, isolated experiments. Gilbert, who first distinguished between magnetism and this force, which he thence called electricity, had indeed essayed to explain the attraction of electrified bodies by the analogy of the melting together of two drops of water. Otto Guericke had discovered that electrified bodies also suffer repulsion, and probably first had seen an electrical spark. Stephen Gray had distinguished between conductors and non-conductors, and had noticed the electrification of bodies by mere presence, by induction. Du Fay had proved that two distinct kinds of electrification might be excited by rubbing different substances, and that the one class of rubbed bodies attracted the other class of rubbed bodies, while each repelled its own kind. Van Kleist had discovered what is now known as the Leyden phial, and Van Musschenbroek had made it famous among all the learned. Winkler had set fire to a number of inflammable substances by means of the electric spark, and many more curious results had been obtained. But futile, indeed, would have been these isolated experiments, if Franklin, and Symmer, and Winkler, and Aepinus, and Wilke, had not set the world agog by a famous contest over the theory of electrical action.

Experiment was opposed to experiment, and explanation to explanation, in the sharp battle for truth between the unitarian and the dualistic theories of electricity. What matter if the contest between them has continued even to our own day, and the true nature of electricity be almost as much an enigma now as then? It has been the great unsolved problem that has stimulated research, and incidentally brought about discoveries of the first magnitude. We learn here, again, that the clear mooting of a scientific theory may have an immense influence on scientific and material progress, in that it provides an aim and suggests a plan for experimentation. Scientific history abounds with examples which might be cited in illustration of this sort of stimulus to progress. You will allow me to divert your attention to an analogous and notable example in the history of astronomy.

When Copernicus found that the conception of the earth's motion around the sun accorded best with his observations of the positions of the planets, and he announced the bold hypothesis, it was opposed on the ground that if the earth moved in an orbit, the fixed stars should also appear to describe small movements on the heavens; in other words, we should be able to determine the parallax, and consequently the distance of the fixed stars in terms of the earth's distance from the sun. No such movement was observable in the stars, and Copernicus was obliged to assert that the stars were so distant and the displacement due to parallax so small that his measurements could not detect the motions. Here was the challenge to the improvement of the instruments and methods used in observing—a challenge which bore the richest fruit. Copernicus could determine stellar position within several minutes of arc, Tycho Brahé within one minute, Bradley within a second or two; and only when Bessel, in 1836, brought it down to tenths of a second, was the distance of a fixed star actually measured. The final proof of the justice of the Copernican statement concerning the immense distances of the stars was, however, by no means the main acquisition to astronomy. Tycho Brahé had laid the foundation for the discovery of Kepler's laws, Bradley had discovered aberration and nutation, and astronomy had advanced to the point of refinement in the measuring process that made the discovery of the law of gravitation by Newton possible. But above all, delicate instruments had been invented and rigorous mathematical methods of observing had been devised, which should remain a rich legacy to physical science for all time.

Thus also in electricity were the arts of observation perfected, and the discoveries multiplied by a ceaseless desire to prove the correct conception concerning the nature of the electrical action. On the one hand, electroscopes, electrometers, unit jars, and other devices for the qualitative and quantitative measurement of this force, were devised by many. On the other hand, it was reserved for Tobias Meyer to suggest and for the great Coulomb to prove that electrical repulsion and attraction followed the rigorous mathematical law of decrease according to the inverse square of the distance. These men were both able mathematicians, but Coulomb in addition made himself the father of electrical measurement by the invention and shrewd application of the torsion-balance, and you shall find that the great discovery he made is fundamental to all electrical theory and practice. Ofttimes this law

Digitized by Google

of Coulomb is hid by the later deductions and by the nearer rules of practice, but if you go back to fundamental conceptions you finally cast anchor in a little mathematical expression borrowed from that which states the law of gravitation. Thus, in the search for the true nature of electrical action, now an ingenious instrument, now a great law is discovered.

It is here to be remarked that although all this was accomplished in electricity, generated by friction, we find scarcely any vestige in our electrical exhibition of this method of production. Indeed, I do not remember to have seen there a single instance of this method of producing electricity. And yet there, as constant reminders, stood the old historical machines and there the educational examples of the "balance à torsion" of Coulomb.

If, now, we seek out the sources of the electricity used in most of the ordinary electrical appliances shown, and used particularly in connection with our devices for communicating thought to a distance, we shall find the voltaic battery silently furnishing a constant supply.

It was in 1790, that Galvani first announced the great discovery which led finally to the development of this new source of electricity. We will not, as has so frequently been done, place this discovery to the account of the mere accident of the twitching of frogs' legs, when touched by metal, as they lay near an electrical machine. That was undoubtedly the occasion of directing Galvani's attention to a new phenomenon; but we must not ignore the fact that Galvani, as a student of medicine, knew something of animal electricity and of electricity in general. For to his interest in animal electricity and to his bias in that direction, we must attribute both his closer study of the occurrence and his theory that the real seat of the electricity was in the nerves of the frog.

It was, however, to Alessandro Volta, that the greater credit was reserved of setting the whole matter in a clear light. Although his first work on this subject bore the title of *Animal Electricity*, he soon directed his attention to the contact of the metals as the cause of the electrical disturbance. With the method of a trained physicist he ceased to use the frogs' legs as electroscope, and showed that still the simple contact of two metals produced an electrical action. You remember the old experiments with two coins of different metals which might either produce an acid taste by contact in the mouth or a flash of light before the eye if it were included in the circuit. With this, Volta's investigation had but just begun. He called attention to the fact that, in this same experiment with the metals in one relation in the mouth the taste was acid, in another relation the taste was that of an alkali, and that moreover the taste *continued* without interruption so long as the contact of the metals continued. This we now recognize as the first glimpse of the chemical action of the electrical current. Intent on clearing up his contact theory of the production of electricity, he studied the effect of contact of various metals, arranged them in a series in which the middle terms might be removed with indifference, and proved that a current could only be produced when a liquid intervened in the series. He discovered the first form of what we now know as the voltaic battery. Everyone knows something of the classical contest between Volta's contact theory and the conception of the animal electricity of Galvani, as well as of that other greater contest between the Volta contact theory and the chemical theory of the battery. It required a commission of the Institute of France, with such members as Laplace, Coulomb and Biot to give full recognition to the immense services rendered to science by Volta's labors.

It is interesting at this time to note that at least three lines of investigation diverge from the standpoint of Galvani and Volta. Galvani was absorbed in animal electricity, and among the number of experimenters who, with renewed vigor, took up this line of research could be reckoned Von Humboldt, who is said to have inflicted on himself a large and painful wound in order that he might study the relation of electricity to animal tissue under normal conditions. If medical electricity, so fully represented at the exhibition by a variety of appliances, has any sufficient reason for its existence, it should have profited by these and a long series of similar researches that followed in Galvani's wake. On the other hand, Volta inaugurated a series of the most refined investigations on the potential of contact, and it is probable that no other electrical question has developed more refined methods of experimentation. Although a brilliant line of physicists, from Volta to Sir William Thomson, discuss and experiment on the question, the mystery is still ours. The third direction given to investigation was, as you know, the chemical one, with its Ritters, its Davys, Becquerels and Faradays.

It would serve no useful purpose to recall the names of a tithe of the chemists and physicists who have step by step developed the voltaic battery as now used. Whether of one fluid or two fluids, of higher electromotive force or of lower internal resistance, it matters not, the battery is the finished product of an hundred willing workers in the field of pure research.

No one who fails to recall the familiar history of electrical progress can have a just conception of the many and widespread ramifications incident to the introduction of the Voltaic method of generating electricity. We have only to pause before one of those large storage batteries of the exhibition to be reminded of the early discovery by Ritter of the polarization of the voltaic cell, and the later developments of polarization, particularly in the hands of Planté, into a factor as useful as it was once inimical. This is but an instance, and very briefly stated, of many lines of research suggested by the battery. We mention next the galvanoplastic processes so rich in utility and beauty, as due to the study and use of the battery in electrolytic action, by Faraday. The electrotypes, electro-plated ware, and all sorts of artistic reproductions, seem fully to repay the wearisome investigations in the field of electro-chemistry.

But, in passing to and fro through the exhibition, we have noticed many appliances which owe their utility to some relation between electricity and magnetism, and Oersted's early experiments with the galvanic battery, and his consequent discovery of a direct relation between a current of electricity and a magnet, can no longer be kept in the background. We here come upon another epoch-making experiment.

It was in the course of preparation for a lecture on "Electricity, Galvanism and Magnetism," in the spring of 1820, that Oersted, as he informs us, first tried the celebrated experiment of the effect of a current of electricity on the magnetic needle. It cannot be said that the discovery was altogether unsuggested by the previous course of science. Franklin had magnetized needles by the passage of the electric spark, and Oersted himself had remarked the uneasy movement of the magnetic needle during a thunder storm. It was then the next step to imagine the influence of the electric current on the needle. Oersted not only exhibited the action of the current on the movable magnetic needle, and conversely by freely suspending a little battery caused it to move by means of a magnet as though itself a magnet, but he brought out clearly the relation of direction of the current to the deflection of the needle. His little pamphlet on the subject, written in the Latin language, and hence at once accessible to all the learned of other countries, produced a profound sensation in scientific circles. Eagerly were the experiments repeated, and with astonishing rapidity were new discoveries added. In Germany, Seebeck, Erman, Poggendorff and Schweigger took up the subject; and the very galvanoscope then made by Schweigger and Poggendorff by coiling the wire a number of times about the movable magnet

Digitized by Google

so as to multiply the Oersted effect, is our current detector to-day.

It was, however, in France that the news of this discovery was to be crowned by developments of even greater moment than the original experiments of Oersted. Arago brought the news to Paris, and, assisted by his friend Gay Lussac, showed that the electric current not only deflected a needle, but magnetized a steel rod when it was passed through a spiral wound round the rod. They also showed that a wire included in the galvanic circuit actually played the part of a magnet in attracting iron-filings. You remember how, similarly, the attendants of some of the heavy current dynamos at the exhibition amused us all by showing the power of a simple copper wire to attract nails, files, and such like. That, we suppose, was but a playful recognition on the part of the dynamo of its high-born blood.

To André Marie Ampère, however, belongs the glory, not merely of making a few novel experiments but of so theorizing upon the experiments made, and of so inventing new experiments according to theory, and as groundwork for the development of theory that he was enabled to put in place the very corner-stone of the science of electro-dynamics.

And just here we must be permitted to say that there could be no better commentary on the powers of mathematical training in determining the best course of progress, than to institute a comparison between the articles of Oersted and of Ampère, as they stand recorded in two successive volumes of the *Annales de Chimie et Physique*, of the year 1820. But for the lucid conceptions of the French mathematician, we might still be speaking of the "electrical conflict" of Oersted. To state a few of Ampère's achievements in electricity: He introduced the convention, which has become permanent, of regarding the direction of the current to be that of the positive electrification. He stated so simple a mnemonic for predicting in what direction the needle will be deflected by a current, that the current always "enters the heels" of the practical electrician, and "flows out at his head," when he "looks upon a needle whose north end is deflected to the left." He found that currents acted either attractively or repulsively on currents, according as those were in the same or in opposite directions. But the most important step taken by him was in introducing an electrical conception of magnetism. Since the needle directed itself at right angles to the current, currents flowing from east to west round the earth must produce its magnetism, while artificial magnets are also to be conceived as formed of molecular currents. The whole question then resolved itself into the simple elements of the action of one current on another. The problem was now one of mathematics and mechanics, and he resolved it with abundant success.

As we leave this eminent contributor to the realities of our exhibition, we cannot omit the beautiful eulogy Clerk Maxwell wrote, when he himself recast the mathematics of the subject: "The experimental investigations by which Ampère established the laws of the mechanical action between electrical currents, is one of the most brilliant in science. The whole, theory and experiment, seems as if it had leaped full-grown and full-armed from the brain of the 'Newton of electricity.' It is perfect in form and unassailable in accuracy, and it is summed up in a formula from which all the phenomena may be deduced, and which must always remain the cardinal formula of electro-dynamics."

We pass now to the next great step that had to be taken before current electricity would become the facile, intelligent servant of the world. This time, also, it is the able mathematician who, in the person of George Simon Ohm, first discloses the wonderfully simple relations existing between the conductivity of a circuit and the electricity passing. There is no practical electrician, however ignorant of the fundamental demonstrations, or of the repeated experimental and theoretical verifications, that does not pin implicit faith to Ohm's law. Electromotive force = current × resistance: is the magical rune now applied in a thousand mystic transformations common to the art and practice of electricity. If space permitted, the line of thought of Ohm's celebrated memoir would be an interesting topic; but we must at least remark that, taking into account the changes in our electrical nomenclature, the very statements of that memoir have now become the familiar conceptions of all who comprehend what is meant by the term "electrical current." Through Ohm, the practice of electricity is also probably a great debtor to no less a mathematician than Fourier; for Ohm himself states how the conceptions Fourier had used in his great work on the theory of heat, were by him transferred to electricity. And we mention this indebtedness in order to be able to hint at the vast obligations due by electrical progress to the prior cultivation of mathematical analysis in other fields. In connection with such an application as that made by Ohm, Fourier's own words seem like a revelation. "Mathematical analysis," says he, "seems to be a faculty of the human mind, destined to supplant the shortness of life and the imperfection of the senses; and what is still more remarkable, it follows the same course in the study of all phenomena; it interprets them by the same language, as if to attest the unity and simplicity of the plan of the universe, and to make still more evident that unchangeable order which presides over all natural causes."

We are now in possession of all the essential elements that go to make up the electro-magnetic telegraph: the voltaic battery, the magnetic action of the current, the laws of that action, and, finally, the law of Ohm. A new interest in all the variety of telegraphic and signaling appliances displayed at our exhibition dawns upon us when thus regarded as the direct and necessary product of researches such as these in the field of pure science. Yet a tithe of the important researches bearing on a line of practice such as that of telegraphy, could not be instanced. Enough has been cited to conclusively show, to what great element in human progress, an exhibition of these practical results is chiefly debtor. But if it is still doubted whether these scientists ever know what they are doing, and for what they are doing it, we must remind you how it was in the very highest realms of pure research that the first suggestion of the magnetic telegraph was made, and also the first actual telegraph line constructed and used. For it was within three months after the knowledge of Oersted's experiment, that Ampère had actually proposed the first plan for a telegraphic communication by means of electro-magnetism. And it was between the astronomical observatory and the physical laboratory at Gottingen that the eminent scientists, Gauss and Weber operated the first practical telegraph line.

The dynamo-electric machines displayed in such variety, and destined to several uses of profoundest interest to us all, will ever remain the prominent features of the exhibition; as in memory, we pass through the fascinating scene. Those dynamos always excited our respect. Their very crudeness did not even detract from this feeling. There was about them a certain masculinity of character that impressed itself on everyone, and gave a tone of work-a-day earnestness to the entire exhibition. This earnestness of spirit was real and gave promise of a vigor of progress for the future, that should equal, and doubtless excel, the historical development of the steam engine.

While the variety of type pleased the mechanical fancy, it did not daze the scientific analysis. However crude or however typical of what the future dynamo may be expected to be, each machine was readily analyzed into its essential elements and the action of these referred to the original principles of science.

There are two great events in science that made the dynamo-electrical machine possible; one is that of the

Digitized by Google

discovery of magneto-electric induction by Faraday, in 1831; the other that of the establishment of the great laws of the correlation of forces and the conservation of energy, during the fourth and fifth decades of this century by a goodly array of mathematical and experimental genius. Without the well-known researches of Faraday on magneto-electric induction and the consequent development of the magneto-electric machine from the early Dal Negro and Pixii types up to the Alliance and Pacinnotti, there could not have been a suitable preparation for the improvements of a Siemens or a Gramme. And as an ever-present reminder of the value and eventual use to mankind of such researches, there should be stamped upon every dynamo the name of Michael Faraday.

Again, it is quite remarkable that the title of Werner Siemens' article, in which he, in 1861, announced the dynamo-electrical or reaction principle, should have read: "Concerning the Conversion of Mechanical Energy into Electrical Current, without the Use of Permanent Magnets." It is but an evidence that the other great discovery in science referred to, had borne one of its legitimate fruits. Everyone is now familiar with the history of the discovery, proof and application of the laws of energy by Mayer, Joule, Thomson, Helmholtz, Clausius, and others; and everyone also with the kind of science these names imply.

We can, therefore, pass on to another definite instance of the fruits of the law of conservation of energy that should be mentioned in this connection. We have already spoken of Ohm's law, which is, of course, also here applicable in the dynamo; but we purposely, hitherto, omitted to mention the second law of electrical currents, because of its peculiarly useful relations to problems concerning dynamo currents. According to this law heat is generated or work performed in any given circuit in the following relation: quantity of heat = square of current × resistance × time. There is scarcely a practical calculation concerning the performance of the dynamo into which this little formula does not enter. It is the key that is constantly in the hands of the practitioner, and that easily unlocks the dynamical riddle of the new engine. This time it is the experimental researches of Joule and Lenz, which first proved the relation, and it is the mathematical skill of Clausius that finally expressed the law as a deduction from principles already known.

It would scarcely add to the force of our main argument if we should go further and show how the whole dynamo-electric engine has been subjected to a series of scientific tests, and of theoretical discussions which are destined to make a special kind of engineering. Enough that we can now, at least with partial insight, derive the scientific origin of the dynamo from the old-time rubbing of a piece of amber.

We must also omit discussion of the deep obligation due by our exhibition to pure research in developing the very steam engine necessary to the generation of the new form of energy. To mention the bearing of Regnault's researches and the influence of the mechanical theory of heat, would lead us far away from the electrical side, and is here unnecessary.

We will, however, as we glance at the work to which the current generated in the dynamo is put, remark that it was in Davy's laboratory that the electric arc was first brought out in all its glory. We now see *hundreds* of arc lamps above and around us. Turning to the soft and beautiful light of the incandescent lamps, we see in imagination the spiral of wire that, under the electric discharge, became glowing in Kinnersley's old air-thermometer. If we see the dynamo current at work in the chemist's hands, we have again to recall Davy's experiments and Faraday's exposition of the laws of electrolysis. If we watch the electric motors, as they drive all sorts of machinery, we are borne back in imagination to the year 1835, and with the great physicist, Jacobi, of St. Petersburg, we go sailing up and down the Neva in a boat propelled by a magneto-electric engine, while we learn from him some of the laws underlying the wonderful result.

It is the ocean cable, only present in our exhibition by proxy, that must next serve as the text for a brief reference to the beneficent influence of mathematical theory in general and of the theory of the potential in particular, in bringing about the great achievements. The practical electrician we have ofttimes met in our wanderings through the exhibition has spoken of electrical "potential" as though that were something to put one's ignorance to the blush. But we have sometimes wondered whether he imagined that the word stood primarily in electricity for a purely mathematical conception, which he now unconsciously regards as a physical fact. Moreover, in the occasional references to the indebtedness of practical electricity to mathematical investigation, we have not been able to give even a partial idea of the theories developed, or of their bearing on practice. The only way in which we can pretend further to supply this omission, is to state, in a few sentences, the influence of a single mathematical conception on the progress of the computation of the electrical forces. Laplace, in treating the attractive forces of gravitation, had used a function essentially proportional to the attractive masses and the simple inverse distance. This function, V, has since become famous for its power in dealing with all problems in which the forces act according to the inverse square of the distance. Green and Gauss first applied it to electrical problems, the latter to a general investigation, comprehending gravitation, magnetism and electricity, and subsequently Sir Wm. Thomson, and others, used it as the very key to the solution of the most difficult problems. Now, to use the cable as an illustration of the practical bearing of researches apparently so far removed from actualities, we find that Sir Wm. Thomson, using the conception of the potential, already in 1855 derived the little formula which expresses the electrostatic capacity of a cable, considered as an immense Leyden jar. We stand amazed when, after the breaking of a cable, we see a vessel sent to mid-ocean, there to put down grappling-irons through miles of water and successfully recover and splice the artery of commerce. But we should not forget the little formula, whose use could point to the very spot where the break must have occurred; and we should not fail to remember the formula's out-of-the-way origin.

As we take our parting glance of the fascinating and successful exhibition, we may sum up all in the statement that electricity is now subject to accurate measurement. The magnetometers, electrometers and galvanometers, and the multiplicity of meters that measure every condition of electrical action, stand as the crowning result of theoretical and experimental electricity. If we ask, why the instruments are of such and such forms, we are referred to the mathematics; if we inquire how they are used, we learn also the necessity of acquiring the art and practice of experimentation. If we inquire upon what general method the measurements are made, we are sent all the way back to the great astronomer Gauss, to learn of him the absolute system of expressing forces, and if we ask for the unit of measure, the yard-stick of the practical electrician, the so-called ohm, we have to intercede with the long line of eminent physicists, beginning with Wilhelm Weber and ending with Rayleigh and Rowland, for a copy of their standards.

In every element of the exhibition we detect the most undoubted relations to pure research; and when we run over the scene even thus cursorily, we behold pure research the presiding genius, on whose behests depend the successful activity of every department of electrical practice here represented.

The lessons to be drawn from this review are evident. Research in America should be raised to a higher plane and such methods adopted to bring about the desired

Digitized by Google

result as may have the sanction of past success. The reason why there are not more American names associated with the progress of physical research (and there are many more in this department than we have had occasion to mention) does not lie in the lack of interest, or the lack of power in the American student. Apart from the materialistic spirit that we all imbibe, there is the lack of the appliances and particularly of the unrestricted devotion that such work demands.

Speaking of appliances it is at least in the separation from first-class scientific libraries that the American student suffers untold inconvenience. European students in physics would be amazed to learn that in an American city of nearly one million of inhabitants, there could not be found a complete set of, say, Poggendorff's Annalen or Crelle's Journal, or an instance of other volumes which it were occasionally desirable to refer to, in order that experimentation might start in at the right point and lead to the right end. Especially, however, do we wish to insist on the fact that sufficient opportunity is not afforded for that jealous, single-minded attention which science requires. It is not that large endowments are not given to erect fine buildings for laboratories or to provide fine instruments. But it is that there are but few foundations which put the man back of the instruments and allow him to devote himself with undisturbed purpose to the work of his laboratory. If you will recall the influence of but one institution where a foundation is provided which places an unhampered man in the laboratory, you will appreciate the justice of these remarks. The Royal Institution of London was founded, we are told, to promote, among other things, scientific research. To do this it founded a professorship, which gave the incumbent free scope to follow out researches of the purest type. You know what has been done for electrical science by its professors, Davy and Faraday. They discovered the decomposition of the fixed alkalies, the laws of electro-chemical decomposition, the fact of magneto-electric induction and the two-fold magnetism of matter, together with a whole body of general information on electrical subjects. You know then how deep a debtor our electrical exhibition was to this single foundation for the promotion of research. It need only be said that the prospect is clearly open of doing not only important service to science, but some day to humanity at large, by diverting some of the American wealth to such noble foundations. May we not hope that our public-spirited citizens will thus endow our own Institute, an institution in many respects similar to the one just mentioned. Such a happy result would certainly show that America was not altogether oblivious of its lasting obligation to the contributions already made toward its material and social progress, by the eminent cultivators of pure research.

MR. WALLACE GOOLD LEVISON'S FOCUSING ARC ELECTRIC LAMP.[1]

Since Sir Humphrey Davy, in 1813, by touching and slightly separating two pieces of carbon, forming the terminals of a powerful voltaic battery, first disclosed the dazzling voltaic arc, the need has always been felt, for experimental purposes, of a steady automatic arc electric lamp, which, until recently, was only and but imperfectly satisfied by the exceedingly delicate, unreliable, and costly clock-work contrivances of Foucault and Duboscq. These, however, are now of more historical than practical interest, for, since the development of the dynamo-electric machine first made possible a broad commercial field for electric lighting, the production of an efficient lamp has appeared of sufficient importance to encourage the unremitting activity of an army of inventors, who, rapidly surmounting the mechanical difficulties of the problem, have developed simpler, more efficient, and, in many cases, purely electro-mechanical devices for feeding the carbons.

Among the earlier of these inventions appeared that of Mr. Charles F. Brush, whose application of the annular clutch was so much like a revelation, that, excluding rack and pinion combinations, its repetition in some modified form is looked for in almost every carbon regulator that is announced as new.

In consequence of this repetition the study of lamp mechanisms seems almost entirely relegated to those concerned in commercial electric lighting; but it is believed that the lamp of which working models are herein first illustrated, will interest even the casual reader.

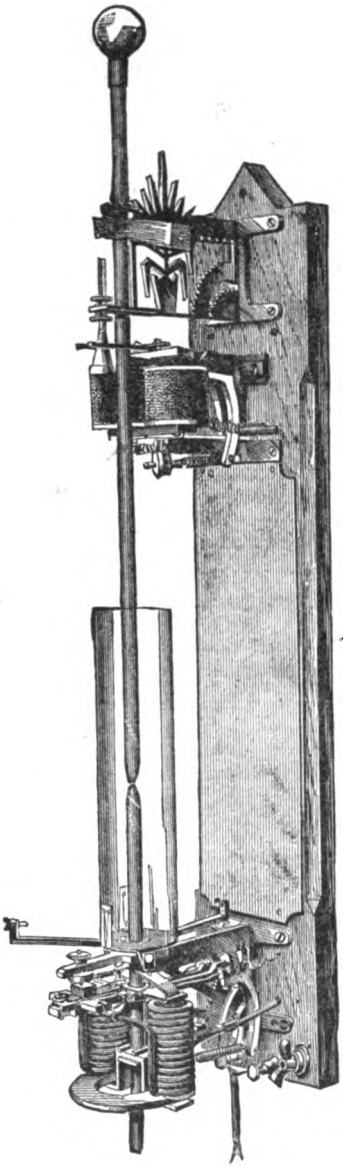

Figure 1.

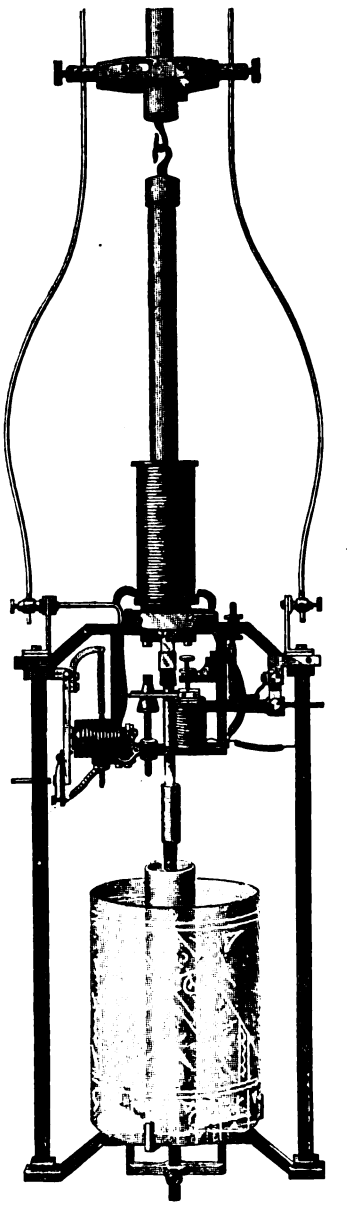

Figure 2.

In figure 1 is shown an ornamental wall or bracket lamp, which may be briefly explained as follows:

The upper bare carbon is clasped by an elastic steel fork, resembling a common tuning fork, which extends from a lever that also carries the armature of a small electro magnet, and is raised upward by a spring. This magnet is wound with two wires at the same time, and when the current from the dynamo is first sent through the lamp, the carbons being separated, its only circuit is through a double wound resistance coil hidden behind the lamp and one wire of this small electro magnet, which

1. United States patents No. 227,025, April 27, 1880; No. 259,811, April 5, 1881; No. 289,425, December 4, 1883; No. 335,968, February 2, 1886; other patents applied for.

Digitized by Google

thereupon attracts its armature and pulls the fork and upper carbon down. A steel cone is so located that the fork spreads open upon it when the armature nearly touches the magnet, and the upper carbon, no longer clasped by the fork, freely drops to contact with the lower carbon. The circuit of the lighting current is thereby closed through the carbons and the coils of a second electro magnet fixed between the lower carbon guides. This electro magnet, wound with coarse wire, is thereby strongly magnetized and attracts its armature, which is also fixed upon a lever raised by a spring. Upon the end of this lever is a spring contact, so arranged, that when the armature is thus attracted, it closes a circuit through which one-half of the shunt current, energizing the upper magnet, is deflected, each half traversing the coils of the upper magnet through separate wires in opposite directions, and thereby demagnetizing it. The upper carbon is therefore raised by the upper spring and lever from the lower carbon, and the lighting arc is produced. As the arc gradually lengthens the lower magnet weakens until its armature is raised by the spring and lever that supports it, and the contacts upon the end of the lever being thereby more or less separated, operate as a variable resistance, and the upper magnet, again energized through the predominance of the permanent branch of the shunt circuit, feeds down the upper carbon as it consumes. In this way the lamp operates indefinitely as a single feed lamp, the lower carbon being held in place by a second fork immovably fixed at the base to the frame of the lamp. Through this fork the lower carbon can be pushed up quite easily if necessary, but the fork is beveled to cutting edges, which bite the carbon firmly, and resist any ordinary effort to push it down. To change this lamp from a single feed to a focusing lamp, it is only necessary to fix upon the lower armature a pair of knife-edged clutches, as shown in figure 1, or upon the lever a third fork. When the lever rises it will then lift the lower carbon with it, and so both carbons will be fed. Instead of the forks, or the clutches shown in the illustrations, annular clamps may be used.

It is apparent that if an upper feed lamp only is required, the coarse wired magnet, with its lever and variable contact, may be removed to another part of the lamp. Figure 2 represents a hanging lamp, in which the magnet is located near the upper mechanism. In this figure is also shown the resistance coil which surrounds the suspending pipe, but being a differential coil it does not magnetize the frame of the lamp. The figure also shows a convenient method of suspending the lamp, and a cut-out switch which permits of its ready removal.

All of the objections which have been suggested by experiments with this lamp have been met, it is hoped, by competent devices, which form the subject of pending patents, and are, therefore, not shown in the figures. They enable the levers to lift the carbons vertically half an inch if desired; provide a device by which the main current is caused to start the light without traversing the resistance coil, and which also operates as automatic cut-out; and provide guides which adjust themselves to irregular carbons. Hence carbons of any desired lengths may be used, and the attention of the trimmer limited at pleasure.

One of the peculiar features of this lamp is the variety of forms it may assume. The variable contact and its heavy magnet may, for instance, be removed from the lamp to any distance, and yet by a turn of its adjusting screw the arc may be reduced, or at pleasure enlarged, to the point of over-crowding the resistance coil. By slightly modifying the construction of the separate variable contact, adding a lower small differential magnet to the lamp, and a proper system of wireing, the focusing lamp may be made so light and compact in construction as to appear, perhaps, especially adaptable for portable use, as in reflector or lantern projections.

Models of the lamp in several forms have been made, but the limit of the present notice permits no further details than a brief mention of some of its probable advantages, which are simplicity and cheapness of construction, absence of the customary counterpoise for the weight of the carbon, and consequent increased length of carbons, and relief to the trimmer; absolute grip of the fork clutch, and consequent little sensibility to jar; avoidance of trouble from wear of the carbon rod when used; facility of adjustment to any dynamo electric current by a simple change of resistance coils; and, finally, facility of change from a focusing to a single feed lamp, or the reverse.

PRACTICAL NOTES CONCERNING THE CONSTRUCTION, USE AND MANAGEMENT OF STORAGE BATTERIES.

BY A. RECKENZAUN.

THERE are, at the present moment, indications which tend to give one the idea that the manufacture of storage batteries is fast developing into a great industry, and, if the existing rate of advance is maintained, we may expect that this new industry will soon become one of national importance. England is now the only country in which secondary batteries are produced on a sound commercial basis, and the progress which has been made is in a great measure due to large pecuniary sacrifices during the early stages of development. By small and apparently insignificant steps, and with great efforts and much unnecessary labor, have these batteries been brought to a certain state of perfection, and there can be no doubt that further improvements will yet be brought about; but such improvements will be sought in the direction of increased durability and reduction in cost of manufacture.

The premature confidence reposed in secondary batteries was long ago destroyed by early failures. Successes during the last two years, however, have had the effect of partially reëstablishing confidence, and we may regard it as a happy incident that a reaction did not set in suddenly, for in that case there would have been a rush for the article, and, in the attempt to satisfy too great a demand without the requisite means of supply, inferior articles would probably have found a market.

How far the storage battery has reëstablished itself in public favor may be gathered from the fact that some £60,000 worth of storage batteries have been legitimately ordered and sold during the past twelve months. This represents, in the aggregate, about 1,000 tons of cells; this amount has been furnished by two or three firms in this country; we take no account of the tons of storage batteries which have not an established reputation, but which may have found purchasers, and others that may still pine in "purgatory."

The importance and desirability of an economical and practical secondary battery has been fully recognized by all who have considered the subject, and it is generally accepted that though there is a considerable amount of loss in the conversion of energy, the undeniable convenience of a method of electrical storage greatly compensates for the attendant waste. Besides the loss of energy, there are two other objections to the employment of storage batteries, and these are first cost and depreciation. How far these objections may be justified, how far they have been removed, and in what direction they may be still further eliminated, will be the theme of these notes.

LOSS OF ENERGY.

It was generally assumed, in times when dynamo machines gave an efficiency of only 70 per cent., that the losses between the shaft of the prime mover and the terminals of the battery amounted to about 50 per cent. of the available power; modern dynamos, however, have an efficiency of 85, and some even 90 per cent. But, in the application of the accumulator as an auxiliary to an installation, we have neither to blame nor to credit the cells with the goodness or the defects of the dynamo; and makers of dynamos

Digitized by Google

would at once inform us that the secondary battery has to stand on its own merits. The efficiency, therefore, of the storage apparatus is a fraction of the total energy supplied to it by the electric generator, and this fraction amounts to not less than $\frac{7}{10}$ or 70 per cent.; in other words, for every 100 watts sent through the cells, 70 watts, at least, reappear as useful work.

Let us express this loss in terms of pence, or a fraction thereof, assuming the source of energy to be coal, at 20s. a ton, converted into mechanical energy through a steam-boiler and engine consuming fuel at the rate of 5 lbs. per horse-power per hour. In round numbers, the cost of coal will come to one half-penny, and, since the steam horse-power has been found to yield sufficient energy, through the medium of a dynamo, to keep eight lamps of 20 c. p. incandescent, the light per lamp hour, as far as coal is concerned, will cost $\frac{1}{16}$ of a penny.

Through the intervention of the storage battery, then, the cost per lamp per hour, in fuel, is raised to nearly $\frac{1}{7}$ of a penny. There is of course also more water used, and a greater wear and tear of machinery if the plant is working 10 hours for charging, and the accumulators alone are to supply light during seven hours without the engine. It is, however, seldom arranged that the engine is to stand idle whilst the maximum number of lights is required, and when the charging machinery is working in conjunction with the accumulator, the latter serving principally as a regulator or safeguard, then only part of the current generated by the dynamo would pass into the cells, and the loss will be less in proportion. Against the objection relating to waste of energy, we may yet place the fact that when only a few lamps out of many are required to be alight, as would frequently be the case in most installations, we need not work the engine and dynamo, the wear and tear of which, as well as cost of attendance, is practically the same whether five lamps are in use or as many hundred. Moreover, if the consumption of fuel constituted the major part of the cost of electric lighting, then, with the above figures before us, we may still stay to consider whether it would be wise to adopt the storage system; but we know that the cost of coal in large installations is less, and in medium-sized and small installations much less than one-half of the total outlay; hence the apparently big waste of 30 per cent. of the available power will appear small in comparison with the sum of items involved in electric lighting, when on an average we may take the value of a lamp hour at one half-penny, or between five and six times the cost of the fuel at the comparatively extravagant rate of five lbs. per horse-power hour and 20s. the ton.

The foregoing is merely an example of a case where steam power has to be expressly put down for the purpose of electric lighting, but there are numerous instances when the advantages of storage batteries outweigh the evil of waste entirely, where they come in not only as a great convenience, but with absolute economy, always providing that their prime cost and maintenance are within reasonable bounds; which must and will be the case so long as the price of lead does not much exceed present rates, and improvements in manufacturing processes continue to be effected. These favorable cases we may now proceed to consider:

First—A case where the available source of power is small, but continuous. There are thousands of factories, works, or mills using steam power throughout the day, and where a small increase of horse-power above the ordinary requirements will hardly be appreciated, and where the hours of darkness, even in winter, do not exceed three or four per day. There a dynamo may run off the common shafting all day with hardly any attention, and accumulate quietly in secondary batteries the energy requisite for lighting the shops in the evening or early in the morning. Again, there may be a small steam engine, gas engine, or a small water wheel or turbine, running continuously for 12 or even more hours a day, the power of which might be inadequate to give light to a given number of lamps by direct application, but energy might be accumulated during the many hours when not otherwise wanted; this would virtually amount to double or treble the power of the source for the few hours when used for lighting or other purposes.

Secondly—A case, local circumstances being favorable, of even greater importance than the first, where power from a natural source would be entirely running to waste; where, in consequence, we should have a decided gain, even were the efficiency of the apparatus not more than 20 or 30 per cent., instead of actually 70 per cent. This is the case with rapidly-flowing rivers and waterfalls in the vicinity of towns, industrial centres, or residences. In the United States some 14,000 h. p. are taken from waterfalls which formerly ran to waste, but now furnish the best of all illuminations; and on the Continent of Europe, also, water power is similarly largely applied; but in none of these advantageous situations are storage batteries as yet used, although they might treble the capacity of the plant. This is principally because the improved batteries are not sufficiently known, and partly because they are still looked upon as being too expensive.

Thirdly—A case where the stored energy is to be utilized when away and disconnected from the generator. Electric cars and electric boats illustrate this case.

These are old stories, dished up afresh; when first told, five years ago, they were mere theories—exercises of enthusiasm; to-day they are realizations. To-day, by this repetition, we record facts. This makes all the difference. —*Electrical Review* (London).

DYNAMO-ELECTRIC MACHINERY.

BY J. HOPKINSON, M. A., D. SC., F. R. S., AND E. H. HOPKINSON, M. A., D. SC.

(Concluded from page 23).

DESCRIPTION OF MACHINE.

THE dynamo has a single magnetic circuit, consisting of two vertical limbs, extended at their lower extremities to form the pole pieces, and having their upper extremities connected by a yoke of rectangular section. Each limb, together with its pole piece, is formed of a single forging of wrought iron. These forgings, as also that for the yoke, are built up of hammered scrap and afterwards carefully annealed, and have a magnetic permeability but little inferior to the best Swedish charcoal iron. The yoke is held to the limbs by two bolts, the surfaces of contact being truly planed. In section the limb is oblong, with the corners rounded in order to facilitate the winding of the magnetizing coils. A zinc base, bolted to the bed-plate of the machine, supports the pole pieces.

The magnetizing coils are wound directly on the limbs, and consist of 11 layers on each limb of copper wire, 2.413 mms. diameter (No. 13 B. W. G.), making 3,260 convolutions in all, the total length being approximately 4,570 metres. The pole pieces are bored to receive the armature, leaving a gap above and below, subtending an angle of 51° at the centre of the fields. The opposing surfaces of the gap are 8 mms. deep.

The following table gives the leading dimensions of the machine :—

	Cms.
Length of magnet limb	= 45.7
Width of magnet limb	= 22.1
Breadth of magnet limb	= 44.45
Length of yoke	= 61.6
Width of yoke	= 48.3
Depth of yoke	= 23.2
Distance between centres of limbs	= 38.1
Bore of fields	= 27.5
Depth of pole piece	= 25.4
Width of pole piece measured parallel to the shaft	= 48.3
Thickness of zinc base	= 12.7
Width of gap	= 12.7

Digitized by Google

The armature is built up of about 1,000 iron plates, insulated one from another by sheets of paper, and held between two end plates, one of which is secured by a washer shrunk on to the shaft, and the other by a nut and lock-nut screwed on the shaft itself. The plates are cut from sheets of soft iron, having probably about the same magnetic permeability as the magnet cores. The shaft is of Bessemer steel, and is insulated before the plates are threaded on.

The following table gives the leading dimensions of the armature :—

	Cms.
Diameter of core	= 24.5
Diameter of internal hole	= 7.62
Length of core over the end plates	= 50.8
Diameter of shaft	= 6.985

The core is wound longitudinally, according to the Hefner von Alteneck principle, with 40 convolutions, each consisting of 16 strands of wire, 1.753 mm. diameter, the convolutions being placed in two layers of 20 each. The commutator is formed of 40 copper bars, insulated with mica, and the connections to the armature so made that the plane of commutation in the commutator is horizontal, when no current is passing through the armature.

Plate 18.—Fig. 3, shows a side elevation of the dynamo ; fig. 4, a cross-section through the centres of the magnets ; fig. 5, a section of the core of the armature, in a plane through the axis of the shaft.

The dynamo is intended for a normal output of 105 volts, 320 amperes at a speed of 750 revolutions per minute. The resistance of the armature measured between opposite bars of the commutator is 0.009947 ohm, and of the magnet coils 16.93 ohms, both at a temperature of 13.5° centigrade ; Lord Rayleigh's determination of the ohm being assumed.

We have now to estimate the lengths and areas required in the synthesis of the characteristic curve.

A_1 ;—from the length of the core of the armature (50.8 cms.) must be deducted 3.4 cms. for the thickness of insulating material between the plates ; the resultant area is, on the other hand, as has already been stated, slightly augmented by the presence of the steel shaft. A_1 is taken as 810 sq. cms.

l_1 ;—this is assumed to be 13 cms : *i. e.*, slightly in excess of the shortest distance (12.6 cms.) between the pole pieces.

A_2 ;—the angle subtended by the bored face of the pole piece at the axis is 129°, the breadth of the pole piece is 48.3 cms., the diameter of the bore of the field is 27.5 cms., and, as already stated, the diameter of core 25.5 cms., thus, the area of pole piece is 1,513 sq. cms., and the area of 129° of the cylinder at the mean radius of 13.0 cms. is 1,410 sq. cms. ; this value is taken for A_2 in the curves drawn on sheet I. (plate 16). In sheet II. (plate 17) A_2 is taken as 1,600, an allowance of 190 sq. cms. being made for the spreading of the field at the edges of the pole pieces, or $\frac{190}{160} = 1.2$ cm. all around the periphery, that is $\frac{1.2}{1.5} = 0.8$ of the distance from iron of pole pieces to iron of core.

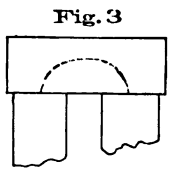
l_2 is 1.5 cm.

A_3 is a little uncertain as the forgings are not tooled all over, it is here taken as 980 sq. cms., but this value may be slightly too high.

l_3 is 91.4 cms.

A_4 is 1,120 sq. cms.

Fig. 3



l_4 is 49 cms., being measured along a quadrant from the centre of the magnet thus :—

A_5 is 1,230 sq. cms., intermediate between the area of magnet and face of pole piece.

l_5 is 11 cms.

ν was determined by experiment as described below, and its value is taken as 1.32 ; when the magnetizing current is more than 5.62 amperes its value should be a little greater.

The function $f(a)$ is taken from Hopkinson, Phil. Trans., vol. 176 (1885), p. 455 ; the wrought iron there referred to was not procured at the same time as, and its properties may differ to a certain extent from, the wrought iron of these magnets.

The curves now explain themselves, the abscissæ in each case represent the line integral of magnetizing force in the part of the magnetic circuit referred to, the ordinates, the number of lines of induction which also pass through the armature.

The results of the actual observations on the machine are indicated, those when the magnetizing force is increasing +, when it is decreasing ⊕. The measurements of the currents in the magnets which were separately excited, and of the potential difference between the brushes, the circuit being open, were made with Sir W. Thomson's graded galvanometers, standardized at the time of use. The irregularities of the observations are probably due to the variation of speed, the engine being not quite perfectly governed. The second construction exhibits quite as close an agreement between observation and calculation as could be expected ; the deviation at high magnetizing forces is probably due to three causes, increase in the value of ν when the core of the armature is partially saturated, uncertainty as to the area A_2, difference in the quality of the iron. It is interesting to see how clearly theory predicts the difference between the ascending and descending curves of a dynamo. Consideration of the diagram proves that this machine is nearly perfect in its magnetic proportions. The core might be diminished by increasing the hole through it to a small, but very small, extent without detriment. Any reduction of area of magnets would be injurious, they might, indeed, be slightly increased with advantage. An increase in the length of the magnets would be very distinctly detrimental. Again, little advantage results from increasing the magnetizing force beyond the point at which the permeability of the iron of the magnets begins to rapidly diminish. For iron of the same quality as that of the machine under consideration, a magnetizing force of 2.6×10^3 or 28.4 per centimetre is suitable. To get the same induction in other parts of the circuit, the diagram shows that for the air space a magnetizing force of 21×10^3 is required, for the pole pieces 0.1×10^3, for the armature 0.2×10^3, for the yoke 0.6×10^3, making a total force required of 24.5×10^3. Any alteration in the length or the area of any portion of the magnetic circuit entails a corresponding alteration in the magnetizing forces required for that portion, at once deducible from the diagram. Similar machines must have the magnetizing forces proportional to the linear dimensions, and, consequently, if the electromotive force of the machines is the same, the diameter of the wire of the magnet coils must be proportional to the linear dimensions. If the lengths of the several portions of the magnetic circuit remain the same, but the areas are similarly altered, the section of the wire must be altered in proportion to the alteration in the periphery of the section.

EXPERIMENT TO DETERMINE ν.

Around the middle of one of the magnet limbs a single coil of wire was taken, forming one complete convolution, and its ends connected to a Thomson's mirror galvanometer rendered fairly ballistic. If the circuit of the field magnets, while the exciting current is passing, be suddenly short-circuited, the elongation of the galvanometer is a measure of the total induction within the core of the limbs, neglecting the residual magnetization. If the short circuit be suddenly removed, so that the current again passes round the field-magnets, the elongation of the galvanometer will be equal in magnitude and opposite in direction.

Digitized by Google

The readings taken were :

Zero ..... 71 left.
Deflection..... .....332 " magnets made.
" .....196 right ; magnets short-circuited.
Hence, deflection to right — 267
" left — 261
Mean deflection — 264

To determine the induction through the armature, the leads to the ballistic galvanometer were soldered to consecutive bars of the commutator, connected to that convolution of the armature, which lay in the plane of commutation.

The readings taken were :

Zero..... .... 23 left.
Deflection..... .....223 " magnets made.
" .....176 } right ; magnets short-
" .....178 } [circuited.
Hence, deflection to right and left — 200

It thus appears that out of 264 lines of force passing through the cores of the magnet limbs at their centre, 200 go through the core of the armature, whence ν equals 1.32. The magnetizing current round the fields during these experiments was 5.6 amperes.

EXPERIMENTS ON WASTE FIELD NOT PASSING THROUGH ARMATURE.

As in the determination of ν a single convolution was taken around the middle of one of the limbs, and connected to the ballistic galvanometer ; the deflections, when a current of 5.6 amperes was suddenly passed through the fields or short-circuited, were :

Zero..... .... 34 left.
Deflection..... .148 " magnets made.
" .... 82 right ; magnets short-circuited.
Hence, deflection to right — 116
" left — 114
Mean deflection — 115

I. Four convolutions were then wound round the zinc plate and the cast-iron bed in a vertical plane, passing through the axis of the armature ; and the deflections noted :

Zero..... ..15 left.
Deflection..... .61 " magnets short-circuited.
" .....40 right ; magnets made.
Zero..... ..11 left.
Deflection..... ..... 64 " magnets short-circuited.
" ....36 right ; magnets made.
Hence, deflection to right — 55
" left — 46
and deflection to right — 47
" left — 53

in the two observations respectively, giving a mean = 50.25; or, reducing to one convolution, = 12.6.

II. A square wooden frame, 38 cms. × 38 cms., on which were wound 10 convolutions, was then inserted between the magnet limbs, with one side resting on the armature, and an adjacent side projecting 5 cms. beyond the coils on the limbs, or about 7·6 cms. beyond the cores of the limbs. The deflections were :

Zero.....34 left.
Deflection.....98 " magnets made.
" ....22 right ; magnets short-circuited.
" ....21 " " "
" .....81 left ; magnets made.
Hence, deflection to right — 56
" left — 64
and " right — 55
" left — 47

in the two observations respectively, giving a mean = 55 ; or reducing to one convolution, = 5.5.

III. The same frame was raised a height of 6.35 cms. above the armature in a vertical plane. The deflections were :

Zero..... 21 left.
Deflection..... 98 " magnets made.
Zero..... ..... 35 left.
Deflection.... ..... 8 right ; magnets short-
Hence, deflection to left — 50 [circuited.
" right — 48
and mean deflection — 46.5
or, reducing to one convolution — 4.6

IV. The same frame was again lowered on the armature and pushed inwards so as to lie symmetrically within the space between the limbs. The deflections were :

Zero..... 32 right.
Deflection..... 112 " magnets made.
" ..... 48 left ; magnets short-circuited.

giving a mean of 80 ; or, reducing to one convolution = 8.0.

Let G represent the leakage through a vertical area bounded by the armature, and a line 7.6 cms. above the armature, and of the same width as the pole pieces ; let R be the remainder of the leakage between the limbs ; then II. and III. give

$$\frac{2}{3}G + \frac{2}{3}R = 5.5$$

$$\frac{2}{3}R = 4.6$$

whence

$$G = 1.35$$
$$R = 6.9$$

Again IV. gives

$$\frac{5}{6}(G + R) = 8.0$$

therefore

$$G + R = 9.6$$

which shows an agreement as near as might be expected considering the rough nature of the experiment, and that the leakage is assumed uniform over the areas considered. We take

$$G = 1.6$$
$$R = 8.0$$

Reducing these losses to percentages we have

$G = \frac{1.6}{115}$	= 1.4 per cent.
$R = \frac{8.0}{115}$	= 7.0 "
And from I. the leakage through the zinc plate and iron base.....	= 10.3 "
Hence the two gaps account for.....	2.8 "
The zinc plate and iron base account for	10.3 "
And the area between the limbs.....	7.0 "
Making a total loss accounted for....	20.1 "
Out of an observed loss of	24.24 "

The leakage through the shaft and from pole piece to yoke, and one pole piece to the other by exterior lines, will account for the remainder.

EFFECT OF THE CURRENT IN THE ARMATURE.

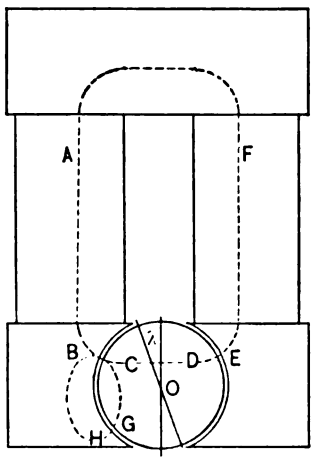
The currents in the fixed coils around the magnets are not the only magnetizing forces applied in a dynamo machine ; the currents in the moving coils of the armature have also their effect on the resultant field. There are in general two independent variables in a dynamo machine, the current around the magnets and the current in the armature, and the relation of E. M. F. to currents is fully represented by a surface. In well-constructed machines the effect of the latter is reduced to a minimum, but it can be by no means neglected. When a section of the armature coils is commutated it must inevitably be momentarily short-circuited, and if at the time of commutation the field in which the section is moving is other than feeble, a considerable current will arise in that section, accompanied by waste of power and destructive sparking. It may be well at once to give an idea of the possible magnitude of such effects. In the machine already described the mean E. M. F.

Digitized by Google

in a section of the armature at a certain speed may be taken as 6 volts, its resistance 0.000995 ohm. Setting aside, then, for the moment, questions of self-induction, if a section were commutated at a time when it was in a field of one-tenth part of the mean intensity of the whole field there would arise in that section, whilst short-circuited by the collecting brush, a current of 600 amperes, four times the current when the section is doing its normal work. The ideal adjustment of the collecting brushes is such that during the time they short-circuit the sections of the armature the magnetic forces shall just suffice to stop the current in the section, and to reverse it to the same current in the opposite direction.

Suppose the commutation occurs at an angle λ in advance of the symmetrical position between the fields, and that the total current through the armature be C, reckoned positive in the direction of the resultant E. M. F. of the machine, *i. e.*, positive when the machine is used as a generator of electricity. Taking any closed line through magnets and armature, symmetrically drawn as ABCDEFA, fig. 4, it is obvious that the line integral of magnetic force is diminished by the current in the armature included between angle λ in front and angle λ behind the plane of symmetry. If m be the number of convolutions of the armature, the value of this magnetizing force is $4\pi C \frac{m}{2} \frac{2\lambda}{\pi}$ $= 4\lambda m C$ opposed to the magnetizing force of the fixed coils on the magnets. Thus, if we know the lead of the brushes and the current in the armature we are at once in a position to calculate the effect on the electromotive force of the machine. A further effect of the current in the armature is a material disturbance in the distribution of the induction over the bored face of the pole piece ; the force along BC, fig. 4, is by no means equal to that along DE. Draw the closed curve BCGHB, the line integral along CG and HB is negligible. Hence the difference between force HG and BC is equal to $4\pi C \frac{m}{2} \frac{\kappa}{\pi} = 2\kappa m C$ where κ is the angle COG. This disturbance has no material

Fig. 4



effect upon the performance of the machine. But the current in the armature also distorts the arrangement of the comparatively weak field in the gap between the pole pieces, displacing the point of zero field in the direction of rotation in a generator and opposite to the direction of rotation in a motor ; and it is due to this that the non-sparking point for the brushes is displaced. A satisfactory mathematical analysis of the displacement of the field in the gap between the pole pieces by the current in the armature would be more troublesome than an *á priori* analysis of the distribution of field in this space when the magnet current is the only magnetizing force. Owing to the fact that the armature is divided into a finite number of sections there is a rapid diminution of the displacement of the field during the time that a section is being commutated, the diminution being recovered whilst the brush is in contact with only one bar of the commutator. The field thus oscillates slightly, owing to the disturbance caused by reversing the direction of the current in the successive sections of the armature. The number of oscillations in a Gramme armature or in a Siemens' armature with an even number of sections will be ρm, where ρ is the number of revolutions per second, but in a Siemens' armature with an odd number of sections it will be $2\rho m$.* This oscillation of the field is only another way of expressing the effect of the self-induction of the section, but it must be remembered that if the self-induction, multiplied by change of current, is expressed as a change in the field we must omit self-induction as a separate term in our electrical equations. The precise lead to be given to the brushes in order to avoid sparking in any given case depends on many circumstances—the form and extent of the pole pieces, the number of sections in the armature, and the duration of the short circuit which the brushes cause in any section of the armature. The adjustment of the position of the collecting brushes is generally made by hand at the discretion of the attendant, and is in some cases fixed once for all to suit an average condition of the machine. We shall therefore, treat λ the lead as an independent variable, controlled by the attendant.

Let I be total induction through the armature, $I + I'$ total induction through the magnets, I' being the waste field. Let C be current in armature, c in the magnets. Let $g I'$ be the line integral of magnetic force from a point on one pole piece to a point on the other, the line being drawn external to the armature, g will be approximately constant. Omitting as comparatively unimportant the magnetizing force in the pole pieces and iron core of the armature we have the following equations :—

$$4\lambda m C + 2 l_2 \frac{I}{A_2} - g I' = 0$$

$$4\lambda m C + 2 l_2 \frac{I}{A_2} + l_2 f\left(\frac{I + I'}{A_2}\right) = 4\pi n c.$$

When $C = 0$ we observed

$$I = \frac{1}{\nu - 1} I'$$

whence

$$g = \frac{1}{\nu - 1} \frac{2 l_2}{A_2}$$

eliminating I'

$$\frac{2 l_2}{\nu A_2}\left(\nu I + 4\lambda m C \frac{A_2}{2 l_2}(\nu - 1)\right) + l_2 f$$

$$\left\{\frac{\nu I + 4\lambda m C \cdot \frac{A_2}{2 l_2}(\nu - 1)}{A_2}\right\} = 4\pi n c + 4\lambda m C \frac{\nu - 1}{\nu}$$

$$-4\lambda m C = 4\pi n c - 4\lambda m C \frac{1}{\nu}.$$

The characteristic curve when $C = 0$ being $I = F(4\pi n c)$ we may write the above as the equation of the characteristic surface thus

$$I + \frac{\nu - 1}{\nu} 4\lambda m C \frac{A_2}{2 l_2} = F\left(4\pi n c - \frac{4\lambda m C}{\nu}\right).$$

In applying this equation it must not be forgotten that

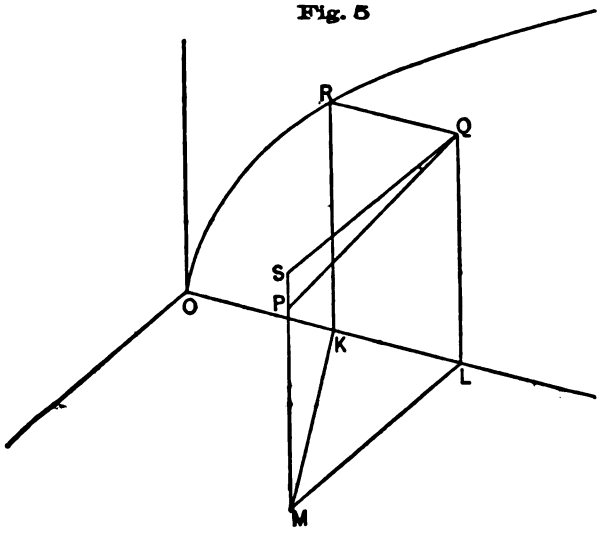
* Added Aug. 17.—Armatures with an odd number of convolutions are open to one theoretical objection, which would be a practical one if the number of convolutions were very small. The $2m + 1$ convolutions constitute in themselves a closed circuit, having a resistance four times the mean actual resistance of the armature measured between the collecting brushes. When any one convolution is exactly in the middle of the field the E. M. F. of the other $2m$ convolutions exactly balance, so that there is upon the closed circuit an E. M. F. due to the single convolution somewhat in excess of $\frac{1}{m}$th part of the actual E. M. F. of the machine. Thus there will be an alternating E. M. F. around the closed circuit of the armature capable of causing a considerable waste of power. This waste is materially checked by the self-induction of the circuit.

Digitized by Google

the E. M. F. of the machine cannot be determined from I unless the commutation occurs at such a time that the coil being commutated embraces all, or nearly all, the lines of induction in the armature.

This equation enables the characteristic surface to be constructed from the characteristic curve. Let O L $= 4\pi n c$, L M $= 4 m \lambda c$, draw M K so that $\frac{K L}{L M} = \frac{1}{\nu}$, through K draw ordinate K R meeting characteristic curve in R, draw R Q parallel to O L meeting ordinate Q L in Q, draw Q S parallel to L M; draw Q P so that $\frac{P S}{S Q} = \frac{\nu - 1}{\nu} \cdot \frac{A_2}{2 l_2}$. Then P is a point on the characteristic surface.

Fig. 5



A very important problem is to deduce the characteristic curve of a series wound machine from the normal characteristic; in this case $c = C$, and we have

$$I + \frac{\nu - 1}{\nu} 4 \lambda m C \frac{A_2}{2 l_2} = F\left\{\left(4\pi n - \frac{4 \lambda m}{\nu}\right) C\right\}$$

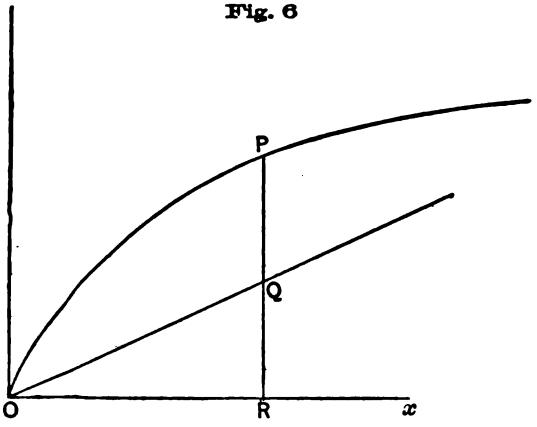
taking P R as ordinate of any point in the normal characteristic, cut off Q R equal to $\frac{\nu - 1}{\nu} 4 \lambda m C \frac{A_2}{2 l_2}$, that is, draw O Q so that

$$\tan Q O x = \frac{\nu - 1}{\nu} 4 \lambda m C \frac{A_2}{2 l_2} \Big/ 4\pi \left(n - \frac{m \lambda}{\nu \pi}\right) C$$

$$= \frac{\nu - 1}{\nu} \frac{A_2}{2 l_2} \frac{\lambda m}{\pi n - \frac{\lambda m}{\nu}}$$

then P Q will represent the induction corresponding to magnetizing force $4\pi \left(n - \frac{m \lambda}{\nu \pi}\right) C$.

Fig. 6



It is noteworthy that as the current C, and, therefore, OR increases, PQ, the induction, will attain a maximum and afterwards diminish, vanish, and become negative. That in series wound machines the E. M. F. has a maximum value has been many times observed. The cause lies in the existence of a waste field not passing through the armature, and in the saturation of the magnet core.

The effect of the current in the armature on the potential between the brushes of any machine is the same as that of an addition to the resistance of the armature proportional to the lead of the brushes, and to the ratio of the waste field to the total field, combined with that of taking the main current $\frac{m\lambda}{\nu\pi}$ times round the magnets in direction opposite to the current c. The preceding investigation tells the whole story of a dynamo machine, excepting only the relation of λ to C in order that the brushes may be so placed as to avoid sparking. The only constant or function which has to be determined experimentally for any particular machine is ν, the ratio of total to effective field, all the rest follows from the configuration of the iron and the known properties of the material.

The following illustrations of the effect of the current in the armature and the lead of the brushes are interesting. In both cases the magnet coils are supposed to be entirely disconnected so that c is zero. First, let λ be negative, short circuit the brushes and drive the machine at a certain speed, a large current will be produced, the current in the armature itself forming the magnet.† Second, let λ be positive, cause a current to pass through the armature, the armature will turn in the positive direction and will act as a motor capable of doing work. In either case, particularly the former, such use of the machine would not be practical owing to violent sparking on the commutator. The following is a further illustration of the formula given above. If we could put up with the sparking which would ensue, it would be possible to make λ negative in a generator of electricity, and thereby obtain by the reactions of the armature itself all the results usually obtained by compound winding.

EFFICIENCY EXPERIMENTS.

Having discussed the relations subsisting between the configuration of the magnetic circuit of a dynamo machine and the induction obtained for given magnetizing forces, and having compared the results obtained by direct calculation with the results of actual observation on a particular machine, the construction of which we have described at length, it appeared of importance to determine the efficiency of the machine under consideration as a converter of energy, when used either as a generator of electricity or as a motor. An accurate determination of the mechanical power transmitted to a dynamo by a driving belt, or of the power given by a motor presents formidable experimental difficulties. Moreover, if the mechanical power absorbed in driving the dynamo be measured directly, any error in measurement will involve an error of the same magnitude in the determination of the efficiency. To avoid this difficulty, we employed the following device.

Let two dynamos, approximately equal in dimensions and power, have their shafts coupled by a suitable coupling, which may serve also as a driving pulley; and let the electrical connections between the dynamos be made so that the one drives the other as a motor. If the combination be driven by a belt passing over the coupling pulley, the power transmitted by the belt is the waste in the two dynamos and the connections between them. By suitably

† Added Aug. 17.—This experiment was tried upon a dynamo machine of construction generally similar to that shown in figs. 3, 4, 5, plate 18, but with an armature of half the length intended in normal work to give 400 amperes 50 volts at 1,000 revolutions. The magnet coils were disconnected, and the terminals of the armature were connected through a Siemens' electro-dynamometer, and the machine was run at 1,380 revolutions. When the brushes were placed in the normal position ($\lambda = 0$) the current due to residual magnetism was 52 amperes. By giving the brushes a small positive lead the current was reduced to nearly zero. By giving the brushes a small negative lead a current of over 234 amperes, the maximum measured by the dynamometer, was obtained, and by varying the lead it was easy to maintain a steady current of any desired amount.

Digitized by Google

varying the magnetic field of one of the dynamos, the power passing between the two machines can be adjusted as desired. If, then, the electrical power given out by the generator is measured, and also the power transmitted by the belt, the efficiency of the combination can be at once determined. By this arrangement the measurement, which

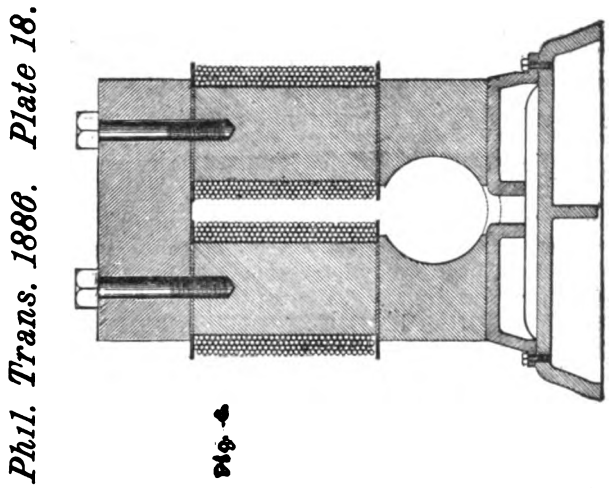


Fig. 4.

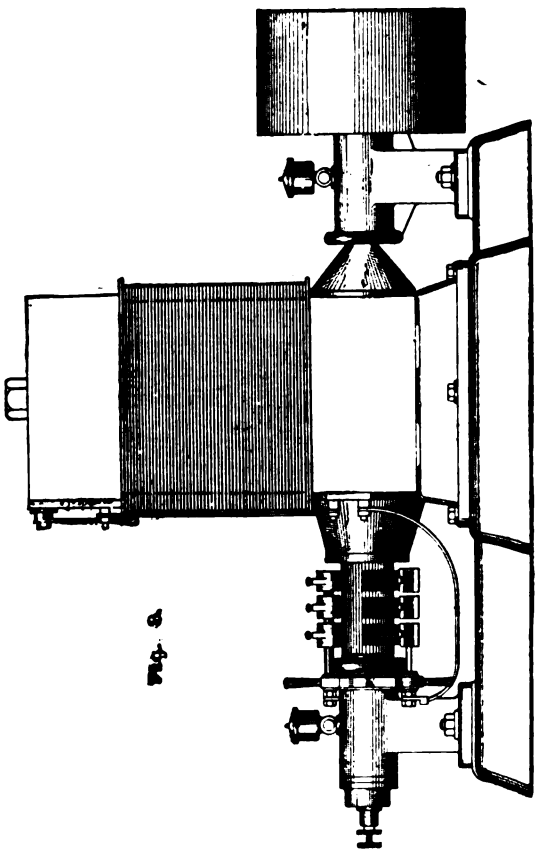

Fig. 6.

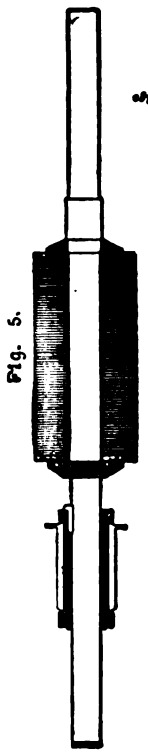

Fig. 5.

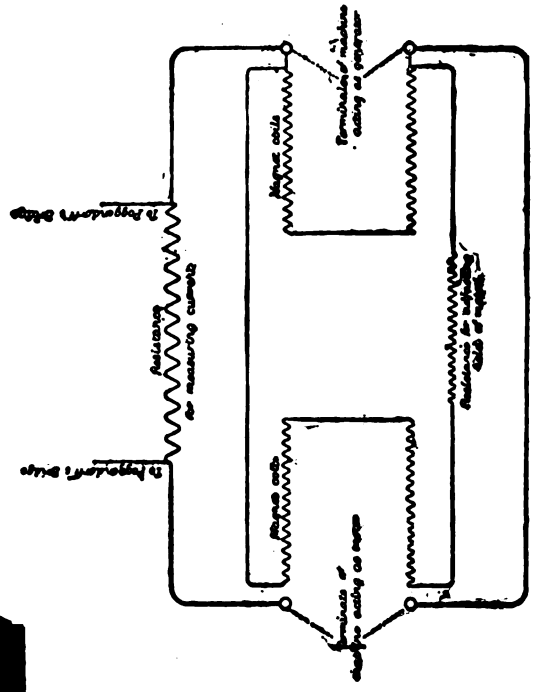

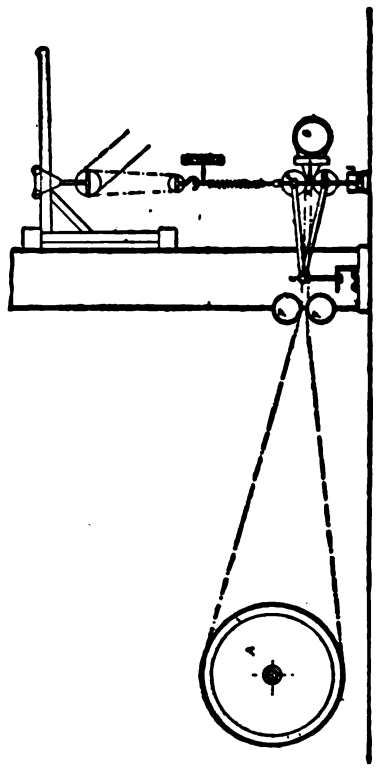

presents experimental difficulties, viz., the power transmitted by the belt, is of a small quantity. Consequently, even a considerable error in the determination has but a small effect on the ultimate result. On the other hand, the measurement of the large quantity involved, viz.. the electrical power passing between the two machines, can without difficulty be made with great accuracy.

The second machine was similar in all respects to that already described, and each is intended for a normal output of 110 volts, 320 amperes, at a speed of 780 revolutions per minute.

The power transmitted by the belt was measured by a dynamometer of the Hefner-Alteneck type, the general arrangement being as shown in the diagram, plate 18. A is the driving pulley of the engine, B the driven coupling of the dynamos; D, D are the guide pulleys of the dynamometer carried on a double frame turning about the fulcrum C, and supported by a spiral spring, the suspension of which can be varied by a pair of differential pulley-blocks attached to a fixed support overhead. When a reading is made the suspension of the spring is adjusted until the index of the dynamometer comes to a fiducial mark on a fixed

Phil. Trans. 1886. Plate 18.

J. & E. Hopkinson.

Digitized by Google

scale, the extension of the spring is then read by a second index attached to its upper extremity ; F, F are two fixed guide pulleys of the same diameter as the pulleys D, D, and having the same distance between their centres, in order that the two portions of the belt may be parallel and the sag as far as possible taken up. The normal from C to the centre line of either portion of the belt between the pulley A and the guide pulleys = 31.9 cms. The normal from C to the centre line of either of the parallel portions of the belt = 2.4 cms.; and from C to the centre line of the spring = 92.7 cms.

Take moments about C ; then

$$\text{Tension of the belt} = \frac{92.7}{34.3} \times \text{tension of spring.}$$
$$= 2.7 \times \text{tension of spring.}$$

Also the diameter of the pulley B = 33.6 cms. and the thickness of the belt = 1.6 cm.

Hence the velocity of the centre of the belt in centimetres per second = 1.845 × revolutions of dynamo per minute, and, therefore,

Power transmitted by the belt in ergs per second
$= 2.7 \times 1.845 \times 981 \times$ tension of spring × revolutions per minute,

assuming the value of g to be 981.

We may more conveniently express the power in watts (= 10^7 ergs per second), and write

Power in watts = .0004887 × tension of spring × revolutions per minute.

The potential between the terminals of the generator was measured by one of Sir William Thomson's graded galvanometers, previously standardized by a Clark's cell, which had been compared with other Clark's cells, of which the electromotive force was known by comparison with Lord Rayleigh's standard. The current between the two machines was measured by passing it through a known resistance, the difference of potential between the ends of the resistance being determined by direct comparison with the Clark's standard cell, according to Poggendorff's method. As experiments were made with currents of large magnitude, it was important that the temperature coefficient of the resistance should be as low as possible. To this end we found a resistance-frame constructed of platinoid wire of great value. The temperature coefficient of this alloy is only 0.021 per cent. per degree Centigrade. (Proc. Roy. Soc., vol. 38, p. 265, 1885.)

The resistances of the armatures and magnets of the two machines are as follows :—

		Ohms.
Generator.....	armature.....	0.009947
	magnets.....	16.93
Motor.....	armature.....	0.009947
	magnets.....	16.44

The resistance of the leads connecting the two machines was 0.00205 ohm, and of the standard resistance 0.00586 ohm.

In all determinations of resistance, the value of the B. A. ohm was taken as 0.9867 × 10^9 c. g. s. units, according to Lord Rayleigh's determination.

The diagram shows the electrical connections between the two machines with the rheostat r inserted in the magnets of the motor dynamo.

In order to ascertain the friction of bending the belt round the pulley B, and of the journals of the dynamo, a preliminary experiment was made with the dynamometer. The combination was run at a speed of 814 revolutions per minute with the dynamos on open circuit and the tension of the spring observed—9979 grammes. The engine was then reversed, and the dynamos run at the same speed and the tension of the spring again observed—3629 grammes. The difference of the two readings gives twice the power absorbed in friction, viz.: 1262 watts for the two machines, or 631 watts per machine. This is excluded entirely from the subsequent determinations of efficiency, as being a quantity dependant on such arbitrary conditions as the lubrication of the journals, the weight of the belt, and the angle it makes with the horizontal.

the percentage loss in the generator magnets; column iii. is the percentage sum of all other losses in the generator; column iv. is the percentage efficiency of the generator; column v. is the percentage efficiency of the motor; column vi. is the percentage efficiency of the double conversion.

In this series of experiments in all cases, from Nos. 1 to 10 inclusive, the brushes, both of the generator and motor, were set at the non-sparking point; but in No. 11 no lead was given to the brushes of the generator, and, consequently, there was violent sparking throughout the duration of the experiment.

In No. 12, the magnets were separately excited with a current giving 113.5 volts across their terminals. The power absorbed must be due entirely to local currents in the core of the armature, and the energy for the reversal of magnetization of the core twice in every revolution of the armature.

No. 13 gives the results of the experiments on the friction of the bearings and in bending the belt already referred to.

It will be observed that the figures in column xiii. are calculated by deducting the power absorbed in the armatures and magnets, and extraneous resistances from the total power given to the combination as measured by the dynamometer. They must therefore include all the energy dissipated in the core of the armature, whether in local currents or in the reversal of its magnetization; also the energy dissipated in local currents in the pole pieces, if such exist; also the energy spent in reversing the direction of the current in each convolution of the armature as they are successively short-circuited by the brushes. Further, it will include the waste in all the connections of the machine from the commutator to its terminals and the friction of the brushes against the commutator. A separate experiment was made to determine the amount of this last constituent, but it was found to be too small to be capable of direct measurement by the dynamometer. Moreover, from the manner in which the figures in this column are deduced, any error in the dynamometric measurement will appear wholly in them. Since, undoubtedly, the first two components enumerated are the most important, and the conditions determining their amount are practically the same throughout the series, the close agreement of the figures in the column are a fair criterion of the accuracy of the observations. Probably 100 watts is the limit of error in any of the measurements. Such an error would affect the determination of the efficiency when the machines were working up to their full power to less than ½ per cent.

It has been assumed that the sum of these losses is equally divided between the two machines. This will not accurately represent the facts, as the intensities of the fields and the currents

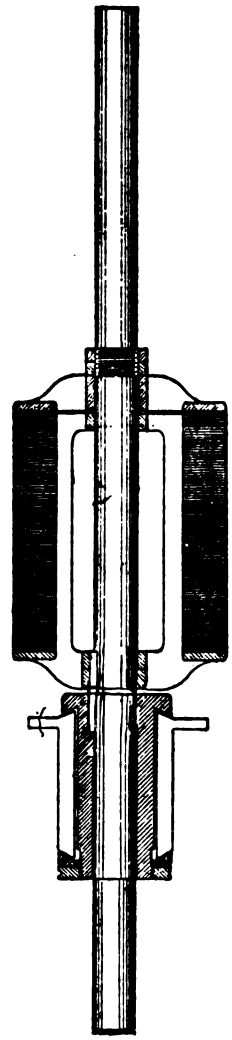

Fig. 3.

passing through the armatures differ to some extent in the two machines. The inequality, however, cannot amount to a great quantity, and if it diminishes the efficiency of the generator it will increase the efficiency of the motor by a like amount, and contrariwise. In No. 11 of the series the effect of the sparking at the brushes of the generator is very marked, the power wasted amounting to at least 250 watts.

If it be assumed that the dissipation of energy is the same whether the magnetization of the core is reversed by diminishing and increasing the intensity of magnetization without altering its direction, or whether it is reversed by turning round its direction without reducing its amount to zero, a direct approximation may be made to the value of this component. (J. Hopkinson, Phil. Trans., vol. 176, 1885, p. 455.)

The core has about 16,400 cubic centims. of soft iron plates, hence loss in magnetizing and demagnetizing when the speed is 800 revolutions per minute $= 16{,}400 \times \frac{800}{60} \times 13{,}356$ ergs per second $= 292$ watts.

Referring to table ii. it appears that the efficiency approaches a maximum when the current, passing externally between the two machines, is about 400 amperes. Let c be the current in the armature, ρ its resistance, w the power absorbed in all parts of the machine other than the armature, then, if the speed is constant, the efficiency is approximately $\frac{EC - w - C^2\rho}{EC}$, where E is the electromotive force. This is a maximum when $\frac{w}{C} + C\rho$ is a minimum, which occurs when $w = C^2\rho$; when the loss in the armature is equal to the sum of all other losses. For the machines under consideration the experimental results verify this deduction. But in actual practice the rate of generation of heat in the armature conductors, when a current of 400 amperes was passed for a long period, would be so great as to trench upon the margin of safety desirable in such machines. Of the total space, however, available for the disposition of the conductors only about one-fourth part is actually occupied by copper, the remainder being taken up with insulation, and the interstices left by the round wire. If the space occupied by the copper could be increased to three-fourths of the total space available, while the cooling surface remained the same, the current could be increased 75 per cent. and the efficiency increased 1.3 per cent. approximately, as all losses other than that in the armature wires would not be materially altered.

The loss in the magnets is also susceptible of reduction. It has already

Digitized by Google

been shown that for a given configuration of the magnetic circuit and a given electromotive force the section of the wire of the magnet coils is determinate. The length is, however, arbitrary, since within limits the number of ampere convolutions is independent of the length. An increase in the length will cause a proportionate diminution in the power absorbed in the magnet coils. If the surface of the magnets is sufficient to dissipate all the heat generated, then the length of wire is properly determined by Sir William Thomson's rule that the cost of the energy absorbed must be equal to the continuing cost of the conductor.

APPENDIX.‡

Since the reading of the present communication, experiments have been tried on machines having armatures wound on the plan of Gramme and with differently arranged magnets, the experiments were carried out in a closely similar manner to that already described.

DESCRIPTION OF MACHINES.

The construction of these machines is shown in plate 20, in which figure 1 shows an elevation, figure 2 a section through the magnets, figure 3 a longitudinal section of the armature. It will be observed that the magnetic circuit is divided. The pole pieces are of cast iron and are placed above and below the armature, and are extended laterally. The magnet cores are of wrought iron of circular section and fit into the extensions of the cast iron pole pieces, so that the area of contact of the cast iron is greater than the area of section of the magnet. The magnetizing coils consist of 2196 convolutions on each limb of copper wire, No. 17, B. W. G., in No. 1 machine, and 2232 convolutions in No. 2 machine. The pole pieces are bored to receive the armature leaving a gap on either side subtending an angle of 41° at the axis.

The bearings are carried upon an extension of the lower pole piece.

The following table gives the principal dimensions of the magnets in No. 1 machine :—

	Cms.
Length of magnet limbs between pole pieces	26.0
Diameter of magnet limb	8.6
Bore of fields	25.7
Width of pole piece parallel to the shaft	24.1
Width of gap between poles	8.6

The armature is built up of plates as in the machine already described, and is carried from the shaft by a brass frame between the arms of which the wires pass.

The principal dimensions are as follows :—

	Cms.
Diameter of core	24.1
Diameter of hole through core	14.0
Length of core over end plates	24.1

The core is wound on Gramme's principle with 160 convolutions, each consisting of a single wire, No. 10, B. W. G., the wire lying on the outside of the armature in a single layer. The commutator has 40 bars.

This dynamo is compound wound, and is intended for a normal output of 105 volts 130 amperes, at a speed of 1050 revolutions per minute. The resistance of the armature is 0.047 ohm, and of the magnet shunt coils 53.7 ohms.

There is here no yoke, and consequently A_4 and l_4 do not appear in the equation.

It is necessary to bear in mind that the magnetizing force is that due to the convolutions on one limb, and that the areas are the sums of the areas of the two limbs. In calculating induction from E. M. F. it is also necessary to remember that two convolutions in a Gramme count as one in a Hefner-Alteneck armature.

A_1 ;—the section of the core is 245 sq. cms., allowances for insulation reduce this to 220.5 sq. cms.

l_1 ;—this is assumed to be 10 cms., but it will be seen that an error in this value has a much more marked effect on the characteristic in this machine than in the other.

A_2 ;—the angle subtended by the bored face of the pole pieces is 139°, the mean of the radii of the pole pieces and the core is 12.45 cms. Hence the area of 139° of the cylinder of this radius is 768.3 sq. cms., add to this a fringe of a width 0.8 of the distance from core to pole pieces, as already found necessary for the other machine, and we have 839.5 sq. cms. as the value of A_2.

l_2 is 0.8 cm.

A_3 is 365 sq. cms. (*i. e.*, the area of two magnet cores).

l_3 is 26.0 cms.

A_5 is taken to be 955 sq. cms., viz., double the smallest section of the pole piece.

l_5 is a very uncertain quantity; it is assumed to be 15 cms.

The expression already used requires slight modification. Inasmuch as the pole pieces are of cast iron a different function must be used. Different constants for waste field must be used for the field, the pole pieces and the magnet core. We write

$$4\pi n c = {}_1 f\left(\frac{I}{A_1}\right) + 2\,{}_2\frac{\nu_2 I}{A_2} + l_3 f\left(\frac{\nu_3 I}{A_3}\right) + 2\,l_5 f'\left(\frac{\nu_5 I}{A_5}\right)$$

the function f' is taken from Hopkinson, Phil. Trans., vol. 176 (1885), p. 455, plate 52. ν_2, ν_3, and ν_5 were determined by experiment as described below, their values are

$$\nu_2 = 1.05$$
$$\nu_3 = 1.18$$
$$\nu_5 = 1.49$$

Comparing the curves on plate 17 with that on plate 19, the most notable difference is that in the present case the armature core is more intensely magnetized than the magnet cores. No published experiments exist giving the magnetizing force required to produce the induction here observed in the armature core, amounting to a maximum of 20,000 per sq. cm. We might, however, make use of such experiments as the present to construct roughly the curve of magnetization of the material; thus we find that with this particular sample of iron a force of 740 per cm. is required to produce induction 20,000 per sq. cm.; this conclusion must be regarded as liable to considerable uncertainty.

The observations on the two machines are plotted together, but are distinguished from each other as indicated. They are unfortunately less accurate than those of plate 17, and are given here merely as illustrating the method of synthesis.

EXPERIMENTS TO DETERMINE ν_2, ν_3, AND ν_5.

The method was essentially the same as is described on pp. 52 and 53, and was only applied to No. 1 machine. Referring to figure 7 a wire AA was taken four times round the middle of one limb of the magnet, a known current was suddenly passed round the magnets, the elongation of the reflecting galvanometer was observed, it was found to be 214 scale divisions, giving 107 as the induction through the two magnet limbs in terms of an arbitrary unit. The coil was moved to the top of the limb as at BB—the elongation was reduced to 206 or 103 for the two limbs. We take the mean induction in the magnet to be 105. A wire was taken three times round the whole armature in a horizontal plane as at CC; the elongation observed was 222 divisions or 74 in terms of the same units. A wire was taken four times round one-half of the armature as at DD; the elongation was 141, or induction in the iron of the armature 70.5, whence we have

$$\nu_2 = \frac{74}{70.5} = 1.05.$$

It may be well to recall here that ν_2 is essentially

‡ Added Aug. 17.

Digitized by Google

dependent on the intensity of the field, strictly the line B on plate 19 should not be straight but slightly curved.

Four coils were taken round the upper pole piece at EE; the elongation was 159, giving 79.5 on the two sides. Coils at FF give a higher result, 87.5, owing to the lines of induction which pass round by the bearings of the

machine, and across to the upper ends of the magnets—r_s is taken to be $\frac{83.5}{70.5} = 1.18$.

The method and instruments were those already described, excepting that the current was measured by a Thomson's graded galvanometer, which had been standardized against a Clark's cell in the position and at the time when used. The resistance of leading wires and galvanometer was 0.034 ohm, the series coils introduced for compounding the machines were also brought into use, and the losses due to their resistance find a place in columns xii. and xiii. in table iii., in which column i. is lead of brushes of the dynamo, positive for the generator, negative for the motor; column ii., revolutions per minute; column iii., deflection of spring in grammes; column iv., watts by dynamometer; column v., volts at terminals of generator; column vi., amperes in external circuit; column vii., rheostat resistance; column viii., watts in generator armature; column ix., watts in motor armature; column x., watts in generator shunt magnet coils; column xi., watts in motor shunt; column xii., watts in generator series magnet coils; column xiii., watts in motor series; column xiv., watts in external resistances; column xv., total electrical power of generator; column xvi., half the sum of losses unaccounted for; column xvii., total mechanical power applied to generator.

Fig. 7

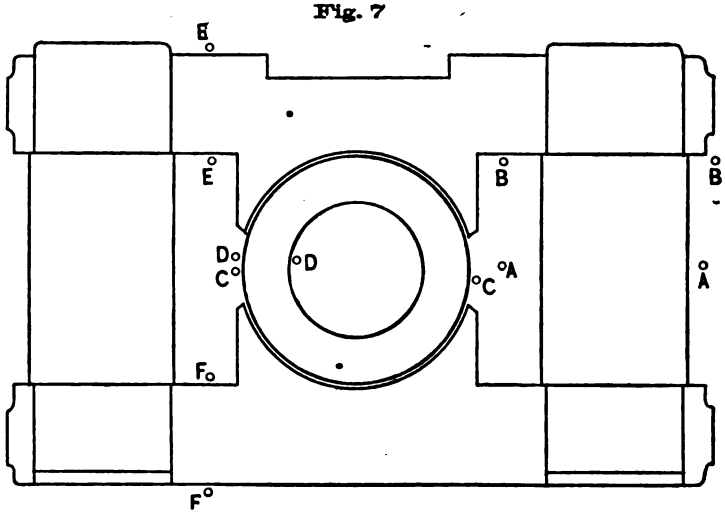

Table iv. gives the losses and efficiencies as percentages in exactly the same way as in table ii., excepting that another column is introduced for the loss in the series coils of the magnets of the generator.

The core of the armature contains about 6500 cub. cms. of iron. Hence energy of magnetizing and demagnetizing when the speed = 1100 revolutions per minute = $6500 \times \frac{1100}{60} \times 13{,}356$ in ergs per second = 159 watts.

In conclusion, we desire to express our indebtedness to Messrs. Mather and Platt, by whom the machines we have used were manufactured, and who, in placing the same at our disposal, together with all facilities for carrying out our experiments at their Salford Iron Works, have enabled us to put theory to the test of experiment on an engineering scale.

THE SO-CALLED "DEAD WIRE" OF THE ARMATURES OF DYNAMO MACHINES.

BY PROFESSOR W. A. ANTHONY.

IT is almost universally taught that that portion of the wire of an armature that does not traverse the field of force, that is, does not cut across the force lines, is "dead wire," and that it should be the aim in designing a dynamo to reduce the amount of it as much as possible. The inside wire of the Gramme ring, for instance, is often referred to as so much waste resistance. The wire that crosses the ends of the Siemens armature is considered in the same light. It has been attempted to improve the Gramme machine by placing pole pieces inside the armature, and we have been taught, on what should be good authority, that the Siemens armature should be of considerable length in proportion to its diameter, though this for other reasons should not be carried to extremes.

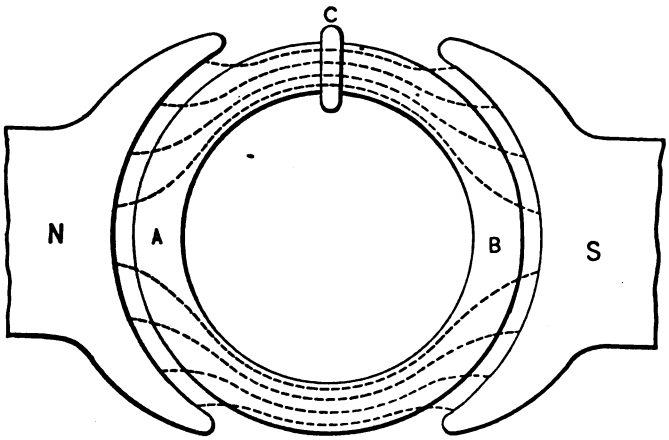
But this whole subject may be viewed from another standpoint, which may cause it to appear in a different light. In all machines except those of the Faraday disc, and the Siemens unipolar types, the moving wire encloses

Digitized by Google

an area through which the lines of force of the field are alternately taken and excluded as the coils revolve. It is demonstrated in all the text books by the familiar assumption of a straight wire sliding across a uniform magnetic field on two fixed parallel rails, which are joined together by a fixed wire at some distant point, so that the whole forms a closed circuit, that the E. M. F. in the moving wire is equal to the area swept through per second multiplied by the intensity of the magnetic field, and, since the intensity of the field is conventionally represented by the number of lines passing through unit area, the E. M. F. in a closed circuit due to motion in a magnetic field, is equal to the number of lines of force taken into or excluded from the circuit per second.

In the Siemens unipolar dynamo, where a conductor moves across the lines radiating from the poles of a magnet, the area enclosed by the circuit is not altered, and the E. M. F. is equal to the number of lines cut per second by the moving conductor. But here only the E. M. F. due to the one length of conductor can be obtained, except by the use of a complicated system of sliding surfaces. In all practical dynamos the moving wire forms a coil, and the E. M. F. developed by its motion is determined by the rate at which lines of force are taken into or excluded from the area enclosed.

Consider the Gramme armature:



Let A B be the iron core, N and S the pole pieces. C one of the coils of wire. Lines of force pass from the pole piece N into the ring, and, following around it, pass out into the pole piece S. These lines pass through the coil C in the position represented, but, as the armature revolves, when C reaches the position B, all the lines have been excluded. Following C through one revolution, it will be seen that all the lines of force are twice included and twice excluded, and if n = the number of revolutions per second, $4\,n\,N$ is the number of lines per second swept through by the coil, where N is the maximum number of lines passing through it; and $4\,n\,N$ is, therefore, the average E. M. F. developed by that coil. To increase the E. M. F. without increasing the speed of rotation, the number N of lines which it includes and excludes must be increased. It is immaterial how they are introduced or discarded, whether by the outer or inner portion or by the edges, and the theory that makes all the wire except that outside the iron ring "dead wire," assumes that the number of lines of force that follow the ring from pole to pole is proportional to the area exposed to the pole pieces, and would be doubled or at least largely increased by presenting pole pieces to the inner surface of the ring. Whether this is probable can be best understood by considering the whole magnetic system of the machine as a *magnetic circuit* in which lines of force are developed by the field magnet coils according to a law similar to that of Ohm for electric circuits. According to this view, iron is the best of all conductors of magnetic lines, but air is by no means an insulator; and in a thick layer of considerable area, as in the space between the pole and iron ring in the figure, the resistance it offers may be small as compared with the iron in other parts of the circuit. The ring itself has a comparatively small cross-section, and moreover the resistance of iron increases greatly with the number of lines of force it has to carry. It may happen that the resistance of the air space between the pole and armature ring shall be less than that of the ring itself. If this be so it would avail little to increase the surface presented to the ring by adding an interior pole piece. Its effect could only be to diminish a resistance that was before only a small fraction of the whole, and the number of lines of force passing through the coils would be only very slightly increased.

Now consider the Siemens armature. To fix the ideas take a particular case. Suppose the mean length of the armature 18 inches, and mean diameter 6 inches. The length of one turn of wire is 48 inches and the area enclosed 108 inches. An armature 12 inches long and 12 inches diameter would require the same length of wire, but each turn would enclose an area of 144 square inches, and supposing the strength of field the same, the coils in the latter case enclose one-third more magnetic lines than in the former. But how would this change of dimensions affect the field. There need be no change in the field magnets. The pole pieces would be changed in form, but the area presented to the armature is not changed. The cross-section of the armature core is the same in both cases. In the 12×12 armature the distance through the core from pole to pole is greater, but, since its circumference is twice as great, the wire will occupy only half the depth, and the air space between the poles and core will be much less. It is safe to assume that the total resistance of the magnetic circuit for the 12×12 armature would be less than for the 6×18, and that the number of lines of force passing through one of the coils of the former would not be less than one and a half times the number passing through the latter. The larger armature, therefore, would need to make only two-thirds as many revolutions per minute to develop the same E. M. F. It would appear, therefore, that *other things being equal*, the best form of coil for an armature would be the form that enclosed the greatest area, with least electrical resistance, that is the circle; such are the coils of the spherical armatures of Thomson & Houston.

It must, however, be remembered that there are three factors determining the E. M. F. of a given machine: armature area, revolutions per minute, and strength of field. These are not wholly independent of each other. The form of armature in itself the best, might not permit the best form of field or the highest speed. The three factors must be considered together, and such a form adopted as will on the whole give the best results.

It must not be inferred from the above, that there is any error in the view that ascribes the E. M. F. of an armature to the cutting of the lines of force of the field by a portion of the wire, while another portion is inactive or "dead." Both methods of viewing the subject are correct, and will lead to the same results if all the factors that enter into the problem are considered. The error lies in the supposition that the dead wire may be brought to life and made to add to the E. M. F. previously existing, by merely presenting to it the pole of a magnet. If those who have expected great things from the pole inside the Gramme armature, had looked at the problem from the point of view of the number of lines that pass through the armature coils, might it not have suggested the question whether the added pole piece would increase that number, or lessen the lines from the outside pole piece by just the number furnished from within.

DYNAMIC ELECTRICITY.

BY CARL HERING.

(Continued from page 13.)

CHAPTER VI.—CALCULATION OF ARMATURES.

From the general principles governing the designing and construction of armatures, which were given in the previous chapter, it will be seen that armatures for generating a definite potential and current may have widely varying dimensions, that is, a number of armatures of entirely different proportions may generate the same potential and current; some one of which will, however, be better than the others. It is not possible, therefore, to lay down a fixed set of rules, by means of which the best proportions of the armature may be determined directly at the outset from the amount of electrical energy to be generated. This must be ascertained by comparing the general calculated proportions of these different armatures with one another, and selecting that one which will be the best under the circumstances. For instance, one armature may have twice as many windings as another, and will, therefore, require half the intensity of field, or half the speed; or it may have half the length, but twice the diameter; or it may have many other combinations of the number of windings, diameter, length, speed, and intensity of field, and yet give the same potential and current. The one which will be the best depends on whether the machine is to be built cheaply, or for the greatest efficiency; whether it may be large and massive, or small and light; or whether the speed may be high, or must be low; in general, it depends on the conditions which limit the construction of the machine. It will, therefore, be different under different circumstances, and must be decided for each case.

It is not necessary, however, to build these different forms in order to find which is the best; it may, in most cases, be ascertained directly from the calculated dimensions. The best and shortest method for ascertaining these proportions is, therefore, to calculate one form, and then to find by calculation how a variation of each one of the principal proportions will affect the ultimate dimensions and speed; it will then be easy, in most cases, to select from these the one which will be the best under the given conditions. In this selection one should be guided by the calculated efficiency of the different forms, by the general proportions of well-constructed armatures, and by the particular style of frame and armature of the machine.

It is difficult to say what is the best order in which the various parts should be determined. It will make very little difference, however, provided the proportions are afterward varied, to see whether they may be improved. In general, the following order may be recommended for cylinder and Gramme armatures. Assume first a certain induction in volts per foot, which is thought to be attainable in that type of machine. Dividing this into the total number of volts to be generated will give the length of the active wire in feet. Assume 70 to 80% of the surface of the armature to be active, that is, embraced by the pole pieces. Dividing the active length of wire by this percentage gives the total length of wire on the cylindrical surface of the armature. From the current which is to flow through the armature determine, approximately, the size of the wire, remembering that the two halves of the winding are in multiple arc, and that, therefore, only half the current flows through each wire. From the length of wire on the cylindrical portion of the armature, and from the diameter of the covered wire, it is easy to ascertain the diameter and length of an armature which will contain this amount of wire on its outside cylindrical surface. The number of layers being always a whole number, which, from the nature of the armature, is limited to very few values, and the circumference of the armature being some multiple of the diameter of the insulated wire, it will generally be found that two or, at most, three trial calculations will enable one to determine the diameter and length of the armature, and, therefore, those of the core.

For cylindrical armatures, a simple deduction will show that the following relation is approximately correct: the length of the wire, in inches, on the cylindrical surface, multiplied by its diameter in inches (including insulation) and divided by the assumed number of layers, is equal to the cylindrical surface of the armature, in square inches, that is, its length in inches multiplied by its circumference in inches. This will enable one to calculate the cylindrical surface, from which the diameter and length can readily be determined, as the circumference must evidently be such a multiple of the diameter of the insulated wire as, when taken together with the number of layers, gives an even number of lengths, equally divided among the commutator bars or coils.

Another method, which will frequently be found to be shorter, is to assume any fixed number of commutator bars, turns per coil, and layers; this will determine the circumference or diameter of the armature. From the number of wires obtained thus, and from the total length required, the length of the armature may then be readily ascertained. If it is found to be absurdly large or small, it is easy to find what changes in the assumed numbers will correct it.

It is assumed herein that there are no iron or wooden lugs or partitions between the coils on the armature; if, however, such lugs are to be used, the circumference of the armature, obtained as described, must be increased by the sum of the spaces occupied by these lugs; that is, by the width in inches of one lug, multiplied by their number.

After having made these preliminary calculations, it is necessary to ascertain whether the resulting proportions of the armature will comply with other conditions which did not enter into the calculations. For instance, from the nature of the armature determine the speed at which it will be safe to run it, and from this, together with the diameter, find the inductor velocity. From the induction in volts per foot assumed at the outset, and from this inductor velocity, determine what the intensity of the field must be. This may be ascertained as follows. Suppose the induction assumed was 1.3 volts per foot, and the inductor velocity 45 feet per second, then any one of the wires will move one foot in $\frac{1}{45}$ of a second. A foot of wire generates 1.3 volts, and, as described in the last chapter, it must cut the field at the rate of 130,000,000 lines of force per second, or in $\frac{1}{45}$ of a second it must cut $\frac{1}{45}$ of this, or about 2,880,000 lines of force. As one foot of wire, in moving a distance of one foot, cuts through one square foot of field, the number of lines of force just determined must pass through one square foot, independently of the actual shape or size of the field; dividing this number by 144 gives the number of lines of force per square inch, that is, the intensity of field required to generate an induction of 1.3 volts per foot at a velocity of 45 feet per second. In this case, the intensity of field will be about 20,000 useful lines of force per square inch, which intensity can readily be generated by properly proportioned and economical magnets.

From the diameter and circumference of the armature, ascertain, approximately, what percentage of the length of one complete winding, or coil, will be active, that is, will lie on the cylindrical surface of the armature, taking care to allow for the extra length required at the heads of a cylinder armature, which for short armatures with many windings will be no inconsiderable amount. Dividing the length of wire on the cylindrical surface determined at the outset, by this percentage, gives the total length. From this, together with the size of the wire, find the resistance of the armature, allowing also for the heating. The square of the current, multiplied by the resistance, gives the loss of energy in the armature, which should be from 2 to 10% of the total energy generated by the machine, depending on its size and on the desired efficiency. If it is found to

Digitized by Google

be much greater, the armature will probably heat badly, being poorly designed for efficiency; if it is less, it shows that a smaller armature could be used, if desired, decreasing some other parts proportionally. A more rational method for determining the diameter of the wire would be to find what its resistance should be from the allowable loss in the armature, and from the current; from this resistance, together with the total length of wire, find its cross-section. But this will frequently be found less convenient, as the length cannot always be ascertained without first assuming some diameter.

Having thus determined roughly the proportions of some one form of armature, which will generate the desired potential, and will not heat too much with the required current, ascertain, by varying such dimension as the nature of the machine will permit, whether the construction of the armature may be cheapened, or whether the efficiency may be increased, or both. As a rule, it is not necessary to make these preliminary calculations with any very great degree of accuracy, as there are a number of factors—such as the self-induction, the heating, the sparking, etc.—which do not enter into the calculation, but which will affect the results. In order to allow for these, as well as for other small errors in calculation, it is advisable to assume a slightly higher potential at the outset. Any small errors made may be corrected in the winding of the field magnets, provided such corrections are not too great to be within the limits of the field.

In series machines the difference of potential at the terminals will be the electromotive force of the armature less the losses in the field coils and in the armature itself. The electromotive force which is used in calculating the armature, should therefore be higher than the difference of potential required by the work to be done, by the amounts lost in the machine itself. The loss in the field magnets may be from two to five per cent. for large well built machines and up to 10 or 15 per cent. in smaller cheaper ones. The same may be allowed for the armature, though it is advisable to make this loss as small as possible, as the sparking generally decreases with the watts lost in the armature.

For shunt wound machines the electromotive force will be reduced only by that lost in the armature, but the current will have to be increased by the amount passing through the field coils. This may be taken from two to five per cent. for large well built machines, and 10 to 15 per cent. in smaller cheaper ones.

(*To be continued.*)

STATISTICS OF UNITED STATES PATENTS ISSUED IN 1886.

COMPILED FOR THE ELECTRICIAN AND ELECTRICAL ENGINEER, BY THOS. D. LOCKWOOD.

THE total number of patents for inventions, in all classes, issued from the United States Patent Office in 1886, is 21,797. The total number issued in 1885 was 23,330. The year 1886 thus shows a decrease of 1,533. The total number of patents issued upon electrical inventions, or in which electricity is applied, is, in 1886, 1,337. Total in 1885 was 1,358. Showing a decrease for 1886 of 21. The electrical patents of 1886 constitute 6.13 per cent. of the whole.

The electrical inventions may be classified as follows:

Conductors, insulators and supports, divided into the following sub-classes:

1. Cables and compound conductors	17
2. Couplings and connectors	16
3. Insulated wire, flexible cords, etc.	12
4. Insulators for pole lines	14
5. Insulating materials and compounds	12
6. Line wire-construction, etc.	4
7. Supports, poles, fixtures and cable hangers	6
8. Underground systems, etc.	44
Total in class	125

The patents relating, in a greater or less degree, to telephony are contained in the following 12 sub-divisions:

1. Battery telephones, or transmitters so-called	68
2. Magneto and receiving telephones	33
3. Telephonic relays and repeaters	4
4. Telephone station apparatus	16
5. Telephone signals	12
6. Telephone exchange systems and circuit arrangements	12
7. Induction remedies, etc	4
8. Individual calls	10
9. Guards against abnormal currents and lightning arresters	15
10. Switchboards	5
11. Miscellaneous telephonic utilizations	32
12. Mechanical telephones	21
Giving a total of	232

Patents showing plans for the distribution of electricity and its utilization in the transmission of power, divided into three sub-classes:

1. Distribution of electricity	35
2. Railways, and motors therefor	55
3. Transmission of power, telpherage, and stationary motors	42
Total	132

Those relating to the generation, development, or storage of electrical energy are in the following sub-classes:

1. Batteries—primary	46
2. " —secondary	22
3. Dynamo and magneto machines	72
4. Dynamo regulators	33
Total, as above	173

Electrical illumination comprises four sub-divisions:

1. Arc lamps	56
2. Incandescent lamps	49
3. Lamps and electric light fixtures	16
4. Lighting apparatus, cut-outs, and similar appliances	36
Total in class	157

In the subject of telegraphy, the following is the result of the year:

1. Autographic, automatic and chemical telegraphs	7
2. Keys, relays, sounders, repeaters, etc.	29
3. Multiple telegraphs	11
4. Printing "	22
5. Novel systems	9
In all	78

The following well-known applications of electricity are bunched as a single class, composed of 11 sub-classes:

1. Annunciators, indicators, and alarms	62
2. Burglar alarms	14
3. Clocks—synchronizing and time systems	53
4. Circuit breakers, closers, changers and controllers	20
5. Electro-magnets, armatures, and induction coils	18
6. Electro-metallurgy	10
7. Fire and heat alarms, and district telegraphs	54
8. Measurement, galvanometers, etc	29
9. Gas lighting	13
10. Railroad signals and train telegraphs	41
In all	314

Unclassified applications, 126.

The grand total as stated above is 1,337.

Telephony is still the most traversed line of electrical invention.

The electrical inventors' names, considered alphabetically, are classified as follows:

Patentees under the initial A = 25; B = 146; C = 76; D = 70; E = 45; F = 59; G = 71; H = 107; I = 2; J = 32; K = 40; L = 58; M = 101; N = 4; O = 4; P = 69; Q = 0; R = 51; S = 133; T = 84; U = 1; V = 36; W = 118; X = 0; Y = 2; and Z = 3.

In 1886 B holds, easily, the place of honor, S, W and H being respectively second, third and fourth. The letter K has made a long forge ahead, apparently on Mr. Knight's electric railway patents; V is indebted to Mr. C. J. Van Depoele for its position. Q and X are, as usual, unrepresented.

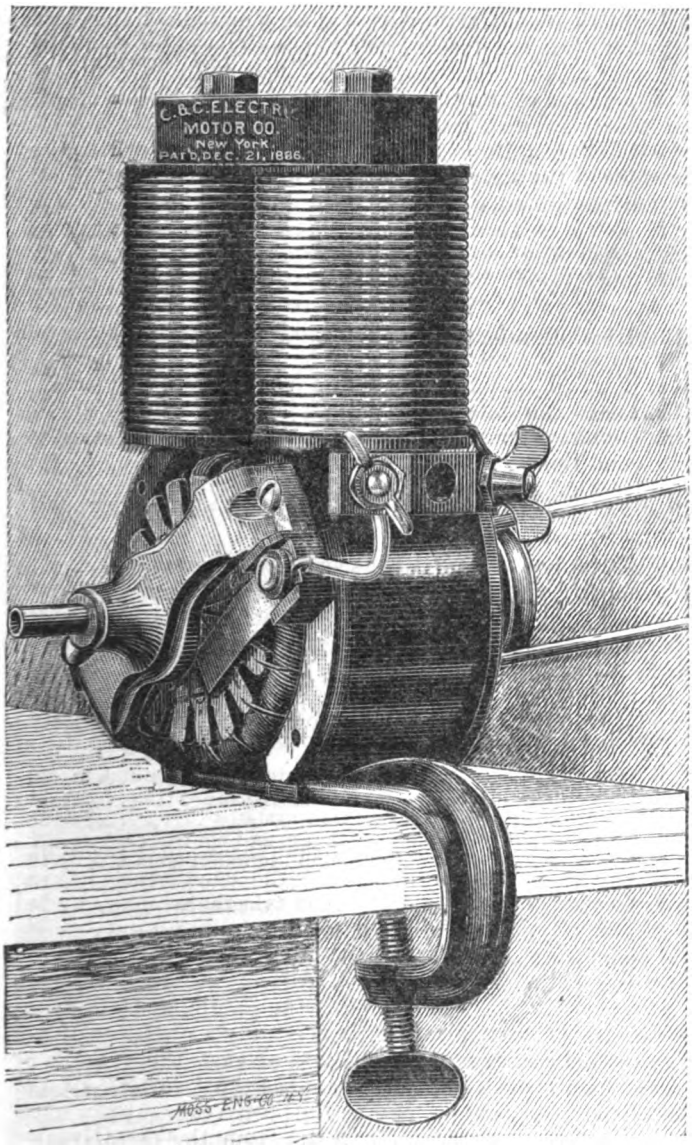
THE "C. & C." ELECTRIC MOTOR.

PUBLIC interest in electric motors is developing with remarkable rapidity. Their construction and introduction are fast becoming prominent features of electrical business. Electric motors of a variety of forms constitute a basis for the inauguration of new manufacturing enterprises in considerable numbers, while established constructors of dynamos are in many cases turning their attention to motors as well.

The extent to which small electric motors have come to be used for sewing machines, fans, dental machinery, and the machinery of small workshops, is quite surprising to those who have not kept the run of the business. Current is supplied either by battery or connection with electric light circuits; the latter method coming rapidly into practice in many cities.



We have recently had an opportunity to examine the motors of the "C. & C." Motor Co. and to visit their factory, by the courtesy of Mr. S. S. Wheeler, manager of the manufactory, and were much impressed by the simplicity and excellence of their motor, as well as by their thoroughgoing and economical methods of manufacture. Both product and processes evince electrical and mechanical abilities of a very high order.

The accompanying illustration shows a motor of the type chiefly made by the "C. & C." company at present. It was designed mainly for sewing machines and other similarly small machinery. The engraving itself is perhaps sufficient explanation of the peculiarities of the machine.

Its weight is 12 pounds, size 7½ x 5 x 3 inches. Capacity up to ⅛ h. p. depending upon the current supplied. Current capacity 20 amperes; speed from 500 to 2,000 turns per minute, according to requirements of use. For an average sewing machine, the speed would be about 1,200 turns. The counter electromotive force generated by the motor running at 1,800 turns per minute, with 18 ampere current in field, is given as five volts. The entire resistance of the machine, the armature and field being in series, is ¼ ohm. The motors are wound to higher resistance for use on incandescent light circuits, the wire being proportioned so that the machine shall be kept to its normal consumption of say 100 volt-amperes. The armature, of the ring type, is wound continuously, wire of trapezoidal section being used in the latest motors. The commutator brushes—as may be seen in the illustration—are so arranged that no injury can arise from reversing the motion of the armature. As will be obvious to the reader, these motors may be run either from a battery or on an electric light circuit The "C. & C." company make and supply a battery specially designed for their motor. The provision of an efficient and convenient battery has been perhaps the chief obstacle to an extensive use of small electric motors hitherto. There have been many reasonably good motors, but few good batteries. In the "C. & C." battery the inconveniences inherent in batteries generally, seem to be reduced to very low, if not their lowest terms. It consists of two cells and is enclosed in a box 8 x 12 x 12 inches. It has an electromotive force of 3.9 volts and a resistance of .06 ohm. It gives a current of 20 amperes through motor held still, and 8½ amperes through motor running at 1,200 turns per minute. The mechanical construction is such that the electrodes may be immersed or withdrawn from the fluid, or maintained at any depth, by means of a lever outside the case, thus providing a means of perfect regulation of speed by the operator of a sewing or other machine. The practice of the "C. & C." company in stamping on every motor or battery made by them a complete statement of its capacity is to be commended.

GLOW-LAMPS: THEIR USE AND MANUFACTURE[1].

BY MAJOR-GENERAL C. E. WEBBER, R. E., C. B.

IT is not my intention to enter into any dissertation on the various kinds of glow or incandescent lamps which have appeared from time to time since their first use by De Moleyns, Starr, and King, between 1840 and 1850, nor do I wish to trouble my audience with the history of the inventions which have led up to the so-called glow-lamp now in commercial use. It is my desire to lead them to realize that in the manufacture of glow lamps we have a rapidly growing industry, in the increase and efficiency of which they may all before long be interested. It is true that the time has not yet arrived when a general audience can be expected to evince as much interest in my subject as they would naturally do in the lectures on candles or lamps, delivered in this hall, but it is believed that a more general knowledge of this very interesting subject will aid in its popularization.

When the glow-lamp was first introduced, its promoters misled the public judgment and eye by claiming for it more duty than it was able to perform. It was shown in exhibitions, where each exhibitor vied with the other in one direction, namely, in creating a blaze of light, where the little glow-lamp was placed alongside the powerful and intense brilliancy of the arc electric light. The exhibition of lamps of 16 to 20 c. p. in groups became the custom, and the public was unconsciously led to compare

1. Abstract of paper read before the Society of Arts, London (Eng.), Wednesday, December 8th, 1886.

Digitized by Google

these, in their minds, with gas jets and Argand burners of far lower real candle-power.

Born and educated in the use of illuminants, which present to the eye a soft wide gaseous flame, having a measurable iridescent surface containing incandescent particles widely dispersed, we were quite unprepared to estimate the increased power of the brilliant little line of intense incandescence that meets our view when we regard this glow-lamp.

Wherever one went, either the gasfittings were made the supports of the glow-lamp, or it was hung from the ceiling, so that on entering a room lighted by a number of these pendants, a brilliant line of light cut the eyes like the blow of a whip lash, rendering everything for a time obscure. Indeed, from careful study of places lighted with the glow-lamp, I have come to the conclusion that the eye is much longer recovering the effects of this sudden slight paralysis of its light receptive powers than is supposed, and that this cry of more light which one hears, where the subject has been dealt with from a gasfitter's point of view, is simply due to temporary observation and loss of power to discover the true needs for illumination of the surrounding objects.

In more than one club in London, where the lines I have referred to have been followed in applying electric light, although the candle-power of the latter is about three times the value of that of the lamps previously in use, there is a constant outcry from the young eyes that "there is not enough light," and from the old eyes that "they know not where to go to avoid the glare."

When regarding this question from the point of view of economy, we see the reason why the cost of electric lighting has so much deterred its use in competition with cheap gas, at the same time the still cheaper arc electric light is ignored or condemned. The screening of glow-lamps from direct vision adds still further to the cost of lighting, but if arc lamps were more used, their cheapness would allow of much light being wasted in concealing their brilliancy by deriving the light only from reflecting surfaces.

The conclusion I have come to, after visiting electric light installations at home and in many parts of the Continent, is that with all kinds of electric lamps used in interiors, the eye ought never to be allowed to meet the source of light, even when subdued 30 per cent. by transmission through obscuring media.

Lately, the council of the Royal Albert Hall has been making a few experiments in the distribution of light within that noble building. Both arc and glow lamps have been tried. The former in the upper, the latter in the lower part of the hall. With the arcs it was found that only in the upper arcade could they be concealed from the eyes of the audience. The effect of brilliantly lighting it up with 12 2,000 c. p. arcs was good, but the light reflected into the body of the hall by the back wall, was probably only one-tenth of that yielded. Six more such lamps placed high up in the lantern, were of no more use than moonlight would have been, but when lowered below the level of the cornice, gave directly or by reflection their full effect. When all the 18 were suspended in a group and let well down into the body of the hall, the illuminating effect on objects was inferior to that of the 32 gas pendants, each with 60 gas jets, which are suspended all round the hall just above the arcade, but when one turned the back to the light the same print was equally easily deciphered.

What the effect of diffusing the light of such a group would have been if the lamp had been confined in an obscure glass lantern remains to be proved. Advocates of concentration and of dispersion of the arc lamps were found. But when it came to the concentration or dispersion of the glow lamps used in the trial, there was little difference of opinion as to the good effect of throwing the light from them towards the backs of the boxes by placing them under the ceilings of each box, and concealing them from the eye of the audience. Some will recall the gloomy cavernous effect of the three tiers of boxes at the Royal Albert Hall. Lighted up, as some of them were, for the trial I am describing, the scene was pronounced fairy-like. The lights were placed so as to be of no inconvenience to the occupants; but the effect was to lighten the whole aspect of the elevation, and as every lamp was concealed, the eye could dwell on features of construction and color, which before were no more than masses of shade.

This concealment of the glow lamps was also carried out on the orchestra stage under the organ, where the trial was equally successful in demonstrating the fact that, although the loss of light may be considerable, by following such a course that loss is a gain, when it can be proved (of which there is no doubt) that the eye is far better able to examine the objects around the concealed lights than if they were exposed.

From the manufacturing point of view, the glow lamp consists of three distinct parts, namely:—The filament; the wire mount or conductor; the glass bulb.

The object of most inventors has been to find a highly refractory substance, and they have all ended in using carbon of either a fibrous or morphous consistency, which they produce in the shape and of the nature which they require, by various processes. The conditions of form, density, uniformity of section, surface, and electrical resistance, with which a glow-lamp bridge must be endowed are now well understood.

So early as 1878 it was discovered or revealed, that in order to be able to use a large number of glow lamps on one system, they must all be subject to the same electrical conditions of tension. It was found that it would be impossible to maintain uniform illumination in all the glow lamps on a system, if each lamp was to be subject to different conditions of pressure; and that the only way to achieve a practical result was to connect one terminal of all the lamps to a main conductor conveying a current in the first place sufficient for all the lamps destined to be used in the system, and in the second place having an E. M. F. or potential above zero (zero being an empirical "earth") of an energy suitable to bring the filament to a state of incandescence; and so arrange that the value of the E. M. F. should be the same throughout. In other words, the system of distribution known as the parallel system was thus practically discovered. The second or return conducting path is, of course, necessary when dealing with a physical development of energy such as what we call "electricity," to complete the circuit to the so-called negative terminal of the dynamo, or other source.

It will readily be appreciated that the word "parallel" is a misnomer, the parallelism of the conductors having nothing to do with efficiency. And that there being carried alongside of one another throughout a building only arises out of a desire to economize the labor of the workmen who have to put them up.

It would, I conceive, be well if the public, and above all the insurance companies (for it is largely a question of fire risk), could be brought to understand that the second or return wire is electrically the same as the "earth" of the electrician, and that so long as the positive, or supply wire, is well insulated and kept far apart from the negative, or return wire, no further precautions are necessary; and when they are thus far apart, even if one is bare, greater security is obtained than by the present system, which unreasoningly insulates the wire which need not be in a state of electrical tension, as well as that which is always ready to discharge. I have digressed a little way to show why absolute uniformity in the glow lamps is necessary to such a system; nothing in its condition could be made to compensate for any defect in that respect. The chief aim then must be to secure this uniformity in the manufacture of the filaments of glow lamps.

In a good glow-lamp, inseparable from uniformity of

Digitized by Google

resistance, are uniformity of surface and incandescence. Uniformity of resistance when hot, means that each lamp will (so to speak) consume the same amount of current, and this can only be secured by electrical measurement under the conditions of uniform electrical pressure. Uniformity of incandescence and surface means that lamps possessing these qualities give almost the same candle-power, and this can only be obtained in the manufacturing processes by visual measurement.

To secure all three, it is necessary to combine a means of visual and electrical measurement. The former is but approximate, the latter is as accurate as a Thomson's galvanometer can make it. In either case, however, when large numbers of filaments have to be standardized, neither measurement can be expected to produce greater accuracy than is essentially necessary for a good commercial lamp; and the fact is that while uniformity of E. M. F. is the condition which must not be departed from, no harm arises in practice if the current consumed and the candle-power is not absolutely uniform. Thus, the required resistance of each lamp is such a resistance as will, under the condition of uniform E. M. F. or electrical pressure, give, with a small varying area of surface, such a candle-power as that to the eye all the lamps are alike when they are incandesced.

This required resistance is obtained by a process known in the electrical world as "flashing," a title which, I believe I am right in stating, owes its origin to Mr. Lane-Fox.

The filaments having been thus standardized, they have to be mounted or attached to the metal conductors, which pass through the glass, and thus make their ends electrically in communication with the outer air. An important condition of the result of any process of doing this must obviously be the obtaining of a good and perfect electrical contact or joint between the metal and the carbon. The absence of this would be fatal to the future of the lamp. Every inventor has labored hard to secure this.

The making of good joints between the ends of electric conductors has been, for the last 30 years, the subject of intense care to every engineer who deals with electricity. No wonder that its importance should be vital in the case of these two little connections, knowing that once sealed up in this bulb they cannot be got at again for repairs, and also knowing the intensity of the current to which they must be the path. In joining iron or copper wires to one another, telegraph engineers long ago knew the difference in the resistance of their lines due to the careful use of soldered joints, instead of leaving them what they call "dry."

Next is the question of the solder to be used, and I believe that no one will dispute that Mr. Lane-Fox was the first to use the process of deposition of carbon by electrically heating the joint in a vessel containing an hydro-carbon surrounding, so as to solder the metal and carbon surfaces to one another. The way in which this is effected is pretty much the same in execution everywhere.

The wire mount of platinum wire, or other suitable metallic conductor, is placed in contact with the carbon filament or bridge, so that they are kept together by any suitable contrivance of their ends, and the joint is then flashed. As any further deposition of carbon on the filament itself would alter the standard effected in the previous stage of the process of carbonization, it will not answer to allow any current to pass through it. This is prevented by any simple means of short circuiting the current, so that it shall only pass through the joint. In the process carried out before you, this is done by this apparatus, which holds the filament in this vessel, which contains hydro-carbon in a liquid instead of in the gaseous form you saw used for carbonization in the previous stage.

Practically, the chemical phenomena are identical in each case, and the result in this one is a perfectly homogeneous electrical joint, larger in section than the other portions of the path of the current, and therefore of ample strength and conductivity to prevent risk of any future wear and tear through high temperature and rough usage.

There is not much to be said about the platinum mount. There are small details in its construction, and the manner of preventing its two sides coming into contact, which vary little in design, and all have the common object. You now see this done by the introduction of the little glass bridge piece. The platinum which should be used, its homogeneity and physical conditions, are all objects of experiment and great care, too minute with which to trouble this audience.

THE BULB.

Having completed this important factor in the construction of a glow-lamp, let us turn to the envelope or bulb, which is destined to be the home of the burner under conditions for supporting combustion opposite to those under which any other means of illumination will act. In the latter, the presence of oxygen in due proportion to the supply of hydro-carbon and other light-yielding gases is vital to its usefulness. In the former, the presence of oxygen within the bulb, and its contact with the carbon bridge, is rapid death, instead of the slow decay, ending in extinction, which is the best that as yet can be expected from the glow-lamp. Imperfect though it may be, it is, however, very good, and not likely to be superseded.

This little glass vessel has also its stages of manufacture, as you will see by the performance in your presence, the power of demonstrating which, together with the processes previously shown, I owe to the permission of the Board of the Anglo-American Brush Electric Light Corporation, whose factory and offices are situated on the Surrey side of the Thames, just over against Charing Cross.

The last stage, namely, the exhaustion, is probably that upon which the life of the lamp most largely depends. This process, exemplified by the action of the mercury pump which you see here, is apparently a very simple one, and would be so, were it not that there are several small impediments to success which, when one comes to demanding a vacuum of one-millionth of an atmosphere, are very serious difficulties.

In the first place, great attention must be paid to the construction of every part of the pump, for, with valves or taps of the ordinary kind, inevitable failure and waste of labor would ensue by leakage when the stage of high vacuum is being approached.

I will avoid going into any description of the merits of the various forms of mercurial air pumps, because Prof. Silvanus Thompson will before long read a paper on that subject before this society.

The best vacuum test is probably that which is made electrically. This is carried out with an induction coil of very high tension, and the test consists in observing when the sparks between two poles of platinum, placed in a part of the pump which shares the vacuum with the lamp under treatment, travels outside the glass instead of inside.

The process of exhaustion in the early days of glow-lamp making, occupied three or four hours; now it has, by better appliances, been reduced in time to a little more than half an hour. The number of lamps turned out in a factory is determined by the number of lamps on each pump, generally three or four, and the number of pumps. Allowing 10 removes a day and 25 pumps, each having four lamps, a manufactory could turn out 1,000 lamps a day. The lamps are next tested and classified for candle-power and voltage, and marked accordingly: formerly 50 per cent. failed to give the standard of efficiency in those respects, now all are up to the mark within 10 per cent.

The electrical efficiency of lamps is measured by the watts expended per candle-power. As is well known, economy in this direction effects a saving for a given amount of light required on an installation of electric lighting, in power converted into electricity, and in the size of the conductors which convey it to the lamps.

Most makers' lamps vary between three and five watts

Digitized by Google

per candle-power, when the lamps are new, under the conditions of voltage which gives the longest life. Those are alleged to be as follows: Edison, five watts; Swan-Edison's, between 3.5 and four watts; Victoria, 3.5 watts; Woodhouse-Rawson, 3.0 watts.

The scientific man does not require to be told what are the tests to which he should subject glow lamps to prove their efficiency. At the Crystal Palace exhibition, at Vienna, at the Health exhibition, and at Philadelphia, very exhaustive tests were applied to the lamps of several well-known makers; but, at the best, all these have proved unsatisfactory, because the makers themselves were not likely to contribute their average lamp, and in some cases either declined to contribute at all, or repudiated the results after they were published.

The tests which require apparatus not usually outside a laboratory are those which observe the E. M. F., the current, the resistance, and the watts per candle-power. There are various arrangements for testing candle-power. I am indebted to Dr. Fleming for that which is shown on the diagram.

The arrangement is a very special one for securing an accurate E. M. F. in the lamp in process of testing. The disc of a photometer is fixed, instead of, as is usual, being left free to slide. The standard flame is a lamp of burning pear-oil, or acetate of amyl, with a flame of regulated height. The lamp to be tested is placed on a carrier which slides along the scale bar.

First, to test the current. The current which feeds the lamps passes along the mains plus and minus, *via* the minus through a Thomson's graded ammeter and a platinoid resistance to one terminal of the lamp. The difference of potential between the termini of the coil is compared with the E. M. F. of a standard Clark's cell on a potentiometer. This latter is a perfect check on the accuracy of the ammeter.

Second, to test the working E. M. F. at the termini of the lamp. Similarly this is made with a Thomson's balance voltmeter, as well as a Thomson's grade voltmeter, checked by measuring the difference of potential at the extremities of a 100 ohm coil in series with a 10,000 ohms coil.

The voltmeters themselves are placed between the terminals of the lamp, but by means of the resistances, the potentiometer with a Clark's standard cell is only compared with $\frac{1}{1000}$th of the E. M. F. of the lamp.

It will be understood that the standard cell in each is the ultimate check on the measuring instruments, provided the resistances are perfectly true, and if the latter do not agree with the former, they have to be re-calibrated.

The need for standardizing the measuring instruments used by electricians has been pressed home by Dr. Fleming to the conviction of every one concerned, but up till now little has been done beyond deliberation by a committee of the Society of Telegraph Engineers and Electricians. At present we do not know that we all mean the same thing when we speak of some of these units of measurement.

Users of glow lamps will be interested in the table shown, which is an average of several tests of the lamps of two or three makers:

ABSTRACTS AND EXTRACTS.

A THEORY OF VOLTAIC ACTION.[1]

THE experiments, as described below, lead to the conclusion that the difference of potential observed near two metals in contact is due to the chemical action of a film of condensed vapor or gas on their surfaces.

Such a pair of metals, with their liquid or quasi-liquid films, are quite similar to a galvanic cell composed of the same metals, and a liquid similar to that of the films, as electrolyte, said electrolyte being divided (in the ordinary static "contact" experiment) by the intervening diaphragm of air or other gas.

In making the experiments, a specially prepared quadrant electrometer was used, having opposite quadrants of the pairs of metals under examination. This instrument was gas-tight (in the ordinary sense), and means were provided for introducing any desired gas or vapor into it, so as to act on the metal quadrants while being tested electrically.

A copper-zinc Volta's condenser, having plates eight inches diameter, was also used. With both instruments the differences of potential near the metals were compared with that of a Daniell cell, represented by the symbol D in what follows:

A number of experiments were made to ascertain the rate of decrease of difference of potential of the films on copper and zinc in air, due to the gradual tarnishing of the metals, the object being to estimate the effect due to clean metals, and compare this with their heats of combustion with oxygen. Although with these metals the comparison holds fairly well, with some others it is only an approximation, which, however, is only what might be expected, seeing that so little is known of the nature of the film and the action taking place in it.

Similar measurements were made with copper and iron in an atmosphere containing hydrogen sulphide. The film on the copper becomes positive as soon as the gas is admitted, and in this particular experiment the difference of potential rose in 1h. 18m. afterwards to .55D. It then fell gradually during eight days to zero, owing to the protecting action of the films of sulphide formed on the metals, the gas being still present. The following (quantitative) results were also obtained in this kind of experiment, where a change in the constituents of the atmosphere surrounding a pair of metals in contact reverses the difference of potential of their films, in correspondence with the reversal of electromotive force which takes place after a similar change in the corresponding liquid electrolyte used with the same metals as a voltaic cell.

Such reversal takes place with pairs of copper-iron when hydrogen sulphide or ammonia gas is added to the air surrounding them; with silver-iron when hydrogen sulphide is added; or with copper-nickel when either ammonia or hydrochloric acid gas is added. The addition of neutral or inert gases has little or no effect, and no exceptional case has been found.

It was sought to annul all electrical effect by varnishing the condenser plates, as had been done in earlier experiments, or by filling the electrometer with naphtha till it covered the quadrants; but the difference of potential did not fall below .29D in the first case and .23D in the second.

Faraday's statement that electrolytic "decomposition and the transferrence of a current are so intimately connected

1. Abstract of a paper by J. BROWN (Belfast), communicated to the Royal Society by Lord Rayleigh, Nov. 18, 1886.

Digitized by Google

that one cannot happen without the other" (*Experimental Researches*, vol. 1, page 252), gives countenance to the idea that the film is of an electrolytic nature, and, therefore, probably water condensed from the air. Two experiments were, therefore, made to test the effect of drying the air round the metals. With a pair of copper-zinc quadrants, inclosed with phosphoric anhydride for 173 days, the difference of potential gradually fell from .659D to .5D. Then, on allowing the instrument to remain open for an hour, the value rose again to .67D, a result quite as marked as might be hoped for with the unsuitable apparatus at command.

Touching more nearly on the nature of the film itself, it was found that when the copper and zinc quadrants were wet with distilled water, their difference was .88D (by calculation from thermo-chemical data it should be about .9D), and when the copper was wet with copper-sulphate solution, and the zinc with zinc-sulphate solution, thus forming a Daniell cell, divided in its electrolytic circuit, the value was almost exactly one Daniell.

The well-known experiment of Sir W. Thomson, where a water-drop was placed between the previously disconnected metal quadrants, is thus easily explained. The water-drop connection equalized sensibly the potentials of the films by altering those of the metals, which were previously at one potential.

This aspect of the Volta condenser as a copper-fluid zinc cell divided in its electrolyte, suggested the possibility of joining the films only on the two metals, without bringing the metals themselves into direct contact, and so producing a real galvanic current-producing cell from the apparently dry metals. After the expenditure of much time and care in bringing the copper and zinc plates to a true surface, cleaning and adjusting them, a current was observed which varied in different experiments from a few up to 130 divisions of the galvanometer used, but which immediately ceased when the plates were either drawn apart or placed in direct metallic contact.

It was found, also, that the "film cell" so produced could be polarized by connection with another battery.

In order to show that electrification is produced without any dissimilar contact of metals, an old experiment of Gassiot's was modified so as to avoid any such uncompensated contacts. The zinc plate of the condenser was joined to the zinc quadrant of the electrometer, and the copper of condenser to copper of electrometer. Now, on altering the capacity of the condenser, a very decided alteration of the difference of potential near the quadrant of the electrometer was observed. It is evident there were electrical charges present, although there was no actual metallic contact at which any electromotive force could (according to commonly accepted theory) have existed to produce them.

CONTINUOUS CURRENT TRANSFORMERS.

It was to be expected that in view of the great commercial success which has attended the use of transformers for alternating currents, electric light engineers should have turned their attention to the question whether it would not be possible to extend the system to continuous currents. If the conversion of high tension currents into those of low tension would be equally easy in either system, it will be evident that the continuous current transformer would receive the preference, because, in this case the energy supplied electrically from the central station would be applicable, not only to lighting, but also to motive power purposes, and to chemical work. Nothing could be more simple in theory than the transformation of continuous currents. We have only to employ a high tension motor, and let it drive a dynamo wound for the desired voltage. But in practice, the double conversion and the necessity of transmitting the whole of the power mechanically from one machine to the other, entails considerable losses. The expense of the plant would also be much greater than the cost of an alternating current transformer, and the regulating device required in order to obtain the low tension current at a fixed voltage, would in all probability, entail considerable complication. To simplify the plant, we could combine the motor and dynamo into one machine, by winding the armature with two circuits, and providing two separate commutators. One winding would be of fine wire, and its commutator would be connected to the high tension mains, whilst the other winding would be of stout wire, and its commutator would be connected to the low tension service leads. In this way no external transmission of mechanical forces from one machine to the other would be necessary, the mechanical forces only acting on the circumference of the armature. This would render it possible to reduce the shaft of the latter to a size just sufficient to carry its weight, thus cheapening the machine and reducing friction. The high tension winding, together with the field magnets, would constitute the motor; whilst the low tension winding, together with the same magnets, would constitute the dynamo; and since the currents in the two circuits on the armature would be in opposite directions, the cross magnetization of the latter would be extremely feeble, and only just sufficiently strong to produce rotation. As a further consequence of this arrangement, the difficulty of sparking would be greatly reduced, and regulation would also be rendered easier. It is very surprising that a simple apparatus like the one here described, has not long ago been manufactured by some of our enterprising dynamo makers. Quite recently, however, a firm in Norwich began to work in this direction, and now that the attention of the trade has been attracted to this matter, others will, no doubt, follow their example. Under these circumstances, it might be interesting to point out that the idea is very old, having, in fact, been used by M. Gramme, and described by the late M. Alfred Niaudet in a pamphlet published in 1875, where the credit of the invention is given to the former. Our contemporary, *L'Electricien*, reproduces a portion of this pamphlet, from which we make the following abstract: "M. Gramme, in the *Comptes Rendus* for the 23d November, 1874, has shown that his apparatus can be used for transforming electricity. He employs for this purpose, a bobbin (armature) wound with two circuits, one of fine and the other of stout wire, and placed between the poles of a magnet. If the current of two Bunsen elements be sent through the stout wire, the ring will begin to revolve, and under the influence of this motion there will be produced in the fine wire coils a current of electricity, in the same way as in an ordinary Gramme machine. In this case the secondary current has a higher electromotive force than the primary one, the ratio being in the machine experimented upon eight to one. It will be seen that we have to deal here with the transformation of electricity, and the change in tension is analogous to that produced by the Rhumkorff coil. With such an apparatus the current of two Bunsen cells can be transformed and made equivalent to a small current from 16 Bunsen or 30 Daniell cells, and employed in telegraphy. It is important to notice that the Gramme apparatus allows not only the transformation of low tension currents into those of high tension but also the inverse, viz., the transformation of a current of high tension into one of low tension. No power is gained by this transformation, because the increase in tension corresponds to a loss in strength of current, and *vice versa*." It is quite evident that, in the foregoing, the principle of continuous current transformers is distinctly foreshadowed, and, by publishing the remarks of the late Alfred Niaudet, we shall probably render a service to would-be inventors, inasmuch as we show them that any attempt at monopolizing such a principle by means of a patent would be useless. On the other hand, there will be many details, especially with regard to the avoidance of sparking and the obtaining of automatic regulation, which must be worked

Digitized by Google

out practically, and where a large field is open for the application of inventive talent. Practical electricians and engineers will do well to turn their attention to the subject. —*Industries.*

ON THE EXPERIMENTS COMMUNICATED BY M. FONTAINE ON THE TRANSMISSION OF POWER.[1]

BY M. MARCEL DEPREZ.

M. Fontaine has lately submitted to the Academy an experiment on the transmission of power by electricity, by means of a process which he considers novel, and which consists in substituting for the generating and the recipient machines a collection of machines connected in series, and in such a number that the sum of their electromotive forces makes up the value which it is desired to obtain. In the experiment in question the number of generators was four, and the number of the recipients three. This idea is far from novel, and it has been proposed by all the electricians who have sought to obtain high tensions without having recourse to the construction of the special machines which I have been the first to realize.

As for the method employed by M. Fontaine to govern simultaneously the four rings of the generators, it much resembles that described in a patent which I took out on April 28th, 1885, in which I gave precisely an example of the application of this procedure to a machine with four rings of 0.30 metre in diameter, and 0.20 metre in length, like those of the machine which served for the experiments in the works of the North of France Railway, in February, 1883. There was thus produced an apparatus, each ring of which could give a force of 1,500 volts at 1,000 turns per minute, the internal resistance of a ring being 5.5 ohms, and the total resistance of the four inducers being 15 ohms. The weight of the acting parts was composed of:

Soft iron	1,124 kilos
Copper	652 "
Total	1,776

On adding 600 kilos for the support, it will be seen that we had arrived at a total weight below 2,500 kilos for a machine with four rings, capable of producing 6,000 volts and 10 amperes at the speed of 1,000 turns per minute. This is half the weight of M. Fontaine's four machines. These results admit of no doubt, since they are obtained by the addition of the effects of identical machines perfectly known.

But this project was not continued, because the conditions laid down for the experiments at Creil were quite different. The machines of M. Fontaine revolved at the speed of 1,300 turns per minute, those at Creil made only 500 turns in the same time. The linear speed of the rings of M. Fontaine is 20.5 metres per second, as against 7.5 metres for those at Creil. If I had given the latter a linear speed of 20.5 metres, they would have yielded an electromotive force exceeding 16,000 volts. The conditions are in no manner comparable, as it will be seen, and, if the Creil machines are heavy, it is simply because only a very low speed is required of them, and nothing has been done to lighten them. If, in the arts, we were to compare machines among themselves, taking lightness as the main condition, the engines of the torpedo-boats would be far superior to those in factories, and yet the use of the latter is far more general, though they are much heavier per unit of power. The reasons for this preference are too evident to require explaining.

In this order of ideas, M. Fontaine's expedient is the same as that of the manager of a factory, who, instead of a single engine of 100 h. p., moving slowly and surely, should prefer to employ four small engines of 25 h. p. each, moving at a very high speed, and acting upon the same shaft by means of mechanical transmissions, having for their object the reduction of the speed.

[1] See Electrician and Electrical Engineer, January, p. 23.

ON THE TRANSMISSION OF POWER: A REPLY TO M. DEPREZ.

BY M. HIPPOLYTE FONTAINE.

M. Deprez has presented some observations on the note of October 26th. These observations, which tend to demonstrate that our experiments present no novelty, either in the methods employed or in the result obtained, may thus be summed up:

1. The process of connecting machines is not novel.
2. The means employed for conducting the rings of the generators much resembles that patented by M. Deprez, April 28th, 1885.
3. Our machines turn too quickly.

Our replies shall be categorical.

1. The method of connecting machines is evidently public property. If MM. Gramme and D' Ivernois patented it in 1872, it was merely that they might not be prevented from using it.

2. The method which we employed for moving the rings of the generators is identically the same as that employed by MM. Chrétien and Félix in their installation for electric ploughing at Sermaize.

3. It is easy to show that there is nothing exaggerated in the speed of our machines, since there now exist more than a thousand Gramme machines which have been working at the same speed for upwards of 10 years without requiring repairs.

What characterizes our recent experiments is not the novelty of the appliances: it is the use of simple dynamos and of well arranged mechanical elements forming a whole not cumbersome, economic to establish, easy to manage, and, in a word, practical.

The result only appears novel: the transmission of 50 h. p. through a resistance of 100 ohms, with a yield of 52 per cent., whilst employing dynamos which together weigh only 8,400 kilos, and cost only 16,450 francs.

If it is true that in industry we employ by preference a machine of 100 h. p., working slowly, in place of four 25 h. p. machines, working rapidly, it is especially to secure an economy in fuel.—*Comptes Rendus.*

GAS AND ELECTRICITY.

In one respect, the recent meeting of the American Gaslight Association fell far short of what should have been. There was no discussion, worthy the name, upon the greatest living question before the gas world—the present and future bearing of the electrical interests upon the gas interests. There was a studied attempt to pass the great question, and it was passed, well-nigh silently. There was a laughing attack made upon the photometric power of the electric incandescents, in the talk ensuing Mr. Boardman's able paper, but even this was quickly turned into an attack upon another interest. The greatest question with which the association should have grappled was left alone.

Such treatment of a living issue comes only from one of two causes—apathy or fear. Either of these is inexcusable. Properly introduced and properly handled, the discussion of the relations which the two interests bear and are to bear towards each other, would have been most fruitful in good results. The experience of some would have well served for the future guidance of others, and the hunger of many a weaker brother been allayed by the crumbs of wisdom and good advice that would have dropped from the lips of those who knew. It was a poor plan that shelved this matter for things of lesser importance.

For the question is one that must be largely met and decided upon before the ten months roll around that lead to another meeting of the American association. The coming year will see far greater progress made by the

Digitized by Google

electrical interests than the sage and sober chroniclers of "electrical accidents" are dreaming of. Inroads into the gas fields will be made to serious extent, unless such be promptly and efficiently met. How to meet these is the question on which the experienced members of the American association should have advised their brethren. The work undone has been left to others, and so far as the duty devolves on us, we are determined that every gas man who reads shall know his danger and the way of escape.

There is a way of escape that is both honorable and, in most instances, easy. This is to recognize the lighting interests as one, and, instead of entering into a combat that will probably end in mutual disaster, to enter into a compact that shall jointly serve the twin interests.

There is no need of repeating old arguments here. It is common fact that the electric arc, at least, largely helps the domestic consumption of gas, and in many cases where the street lighting has been lost to a gas company, its annual output has still shown a larger increase than in any previous years. How much better, in such cases, to make this increase in output, and still own the street-lighting plant? It takes little reason on the part of those who can reason to see the clearness of this. Nor does it take much more reason to see the way to such consummation.

The electric lighting companies are antagonistic to the gas interests, in a great measure, because the latter originally forced such a condition of things. There are those, supposably interested in the well-doing of the gas companies of the country, who have been holding their rushlight so close to the eyes of many of the older gas managers that the latter have failed to see clearly beyond, and have trusted in the assertions that it would yet prove an easy matter to whistle electricity down the wind. As we have had occasion to say before, air gas will not do as a means wherewith to combat electricity, and wind alone is a poor weapon. The misguided gas managers are finding this out, and, with purpose well-concealed, there are to-day not a few who have openly denounced the electric light, furtively making terms for that union of interests in their own cases that we openly advocate for all.

The electrical managers are becoming aware of the benefits arising from a union of interests, and they will not be slow to embrace fair opportunities. But we do not advise such a union as will necessitate a vast watering of stock and a holding up of a high price for gas to secure payment of dividends on fictitious values. There are instances wherein such procedures are, in greater or less extent, necessary; but these are the exceptions, and not the rule. What we advocate is the installation, on the part of every gas company, of its own electrical plant. Begin first with an arc system, following up, as convenience may dictate, with the smaller lamps, thus giving consumers the choice of means for illumination, and holding all the vantage ground within the company's grasp. In very many cases this can be accomplished without inflation of stock, or issue of bonds; and we need not state the effect upon the dividend-earning power of such a company.—*Light, Heat and Power.*

A PROMINENT GASLIGHT OFFICIAL ON ELECTRICITY.

"Is it true that your corporation proposes entering the business of electric lighting?" was asked by a *Journal* representative, yesterday, of a prominent official of the Boston Gas Co.

"Well, it is true," was the reply, "that we have decided to ask the next legislature for authority to produce electricity; and that will be for electric power as well as light."

"Have you found any decrease in the consumption of gas since the introduction of electric light in Boston?"

"There are many places where electricity has come into use, but in most of them gas is used also, and the consumption of gas has been extended in newly-developed sections, so that there has been no decrease, but rather an increase."

"Do you find that some stores have increased the brilliancy of their gas lighting on account of rivalry with those that use electricity?"

"Yes; that is doubtless the case in some places."

"Is electricity used on account of cheapness?"

"No; it is not so cheap a light as gas, but it may be called more novel, and it gives less heat."

"Then you do not purpose changing from gas to electric lighting?"

"No; we intend to have the power to produce both, and then to decide according to developments. There are improvements constantly going on, so that those who begin with the electric light now are liable to have to change their whole plant on account of some change in method."

"Do you consider that methods of using gas are also susceptible of improvement?"

"Yes; both in the process of production and the manner of use."

"Do you suggest the use of the new burners which have been introduced into Boston?"

"No; we never interfere with consumers, although new devices are constantly brought to our attention."

"Have you any intention of manufacturing water gas?"

"No; unless the cost of labor should be increased."

"What do you find as to the comparative cost of water gas and coal gas?"

"We can make coal gas fully as cheap, and in doing so we give employment to more men."

"Is gas likely to come into general use for other purposes besides illumination?"

"Yes; for example, it is now used to advantage in gas engines, in which the motive power is gained by a series of regulated explosions. These have not come into use so much in Boston as in some other sections. It is also valuable for heating and cooking."

"Does the franchise which you expect to secure include the distributing of electric power?"

"Yes; I think the future of electricity is more in the line of motive power than of light."

"Will the new projects involve any change in the corporation, or any increase of capital stock?"

"That is something to be considered hereafter. At present, we only wish to apply for the authority. As to the stock, we have a considerable amount unissued now which can be made available in carrying out any new development of our work."—*Boston Journal*, December 8th.

ELECTRIC TRAMWAYS COMING.

If all we read is true, and we have no reason to doubt it, we are bound to acknowledge that our transatlantic cousins are far ahead of us in the application of electricity as a motive power for tramways, and, though the *systems* in vogue may not bear the mark of originality, the spirit with which the various enterprises have been undertaken is truly characteristic of the nation. The number of electric tramways in the United States of America can be counted by dozens, most of which are working successfully and with surprising economy. Several of these lines have been in operation for a couple of years, others are of a more recent origin, and a few are still in the "experimental stage." The Americans are fond of *systems*, but, as far as our own observations go, we often find it hard to distinguish between them; the differences consist not, as the uninitiated would suppose, in the application of various distinct principles, but more in the variation of designs, some of which, for the sake of variety, are of extraordinary appearance, and the changes relate mostly to peculiarly-shaped details in the modes of suspension of motors under the cars, and in the mechanical gearing used between the motors and driving wheels.—*Electrical Review* (London).

AN ELECTRIC LIGHT TIME METER.

L'Electricité describes a new meter for electric light circuits, as follows:

M. Aubert, a clockmaker of Lausanne, has solved the question of a meter in a different manner to any of those hitherto constructed. He substitutes for the measure of the quantity of electricity a precise measure of the time during which the circuit is closed. The apparatus is very simple. It consists of a clock arranged to go only when the circuit is closed. The meter consists of a round metallic box of 10 centimetres (3½ inches) diameter, enclosing a clock movement capable of working for 200 hours. The movement works four wheels indicating by four dials minutes, hours, tens and hundreds of hours. An electro-magnet serves as a detent. The meter box is fitted with two claws, by means of which it can be fixed by two screws against any wall. It is sufficient to pass a plumb-line through the centre of the two marks at the top and bottom of the apparatus, in order that it should be ready to work. The meter box is pierced with two holes, through which the wires attached to the electro-magnet pass. At the instant of closing the circuit, by the action of the switch, the electric current excites the electro-magnet, which immediately attracts the armature; this latter, by its own motion, releases the detent of the pendulum, which is set going, and the meter indicates in minutes, hours, tens and hundreds of hours, the exact time during which the current has passed. At the precise moment when the current is interrupted, the armature, acted upon by a spring, and being no longer attracted by the electro-magnet, resumes its normal position, and the movement of the pendulum is arrested.

LONG-DISTANCE TELEPHONY.

The American Telephone and Telegraph Co., A. S. Hibbard, gen'l superintendent, in a circular dated January 27th (received too late for proper classification) announces the completion of a system of long-distance telephone lines, extending from New York to Philadelphia, Camden and vicinity, and to Stamford, Norwalk, Bridgeport, Birmingham, Ansonia, New Haven, and other points in Connecticut, by means of which subscribers to the Telephone Exchange in New York city may communicate directly with exchange subscribers at any of the above points.

The circular contains the following information:

The successful working of the long lines has been accomplished by the use of two wires in metallic circuit for each connection, and, with local metallic circuits at each end, equipped with "long-distance telephones," perfect service can be secured.

With a special metallic circuit connection in New York city, satisfactory service may be had in conversation with exchange subscribers in Philadelphia or New Haven and vicinity.

Connections from Metropolitan Telephone Exchange subscribers in New York to subscribers in Philadelphia or other exchanges connected, will be satisfactory, provided the subscribers' lines are free from the temporary interferences to which all grounded city wires are liable, and which can only be avoided by use of two wires connected in metallic circuit.

Three classes of "long-distance" service are, therefore, offered to the public. First, with metallic circuit connection at both ends. Second, with metallic circuit connection at one end. Third, with local grounded circuits at both ends.

Metallic circuits, equipped with complete cabinet sets of long-distance telephones, in direct connection with the office of this company, will be furnished at a rental of five dollars per month, if within one-half mile of the central office.

The following are the message rates from New York, each message entitling the sender to five minutes conversation:

Stamford and Norwalk	$ .50
Bridgeport, Birmingham and Ansonia	.60
New Haven	.75
Philadelphia and Camden	1.00

The above rates will be charged for service between the hours of 8 A. M. and 6 P. M.

Night service, between the hours of 6 P. M. and 8 A. M., 50 cents for each message.

Rates to other points furnished on application to the chief operator.

On monthly accounts, for the business done within the month, the following discounts will be made:

All messages over	20	and not over	30		10%	discount.
"	"	30	"	"	40	20%	"
"	"	40	"	"	50	30%	"
"	"	50				40%	"

A supplementary announcement of special connection to the stock exchange is made as follows:

A complete cabinet set of long-distance telephones has been placed in the New York Stock Exchange, in direct metallic circuit connection by the lines of this company to the Philadelphia Stock Exchange and the Philadelphia Telephone Exchange. Competent attendants are in charge to call members as desired. Conversation can be carried on with parties in Philadelphia free from induction or the disturbing effects incident to grounded circuits. The service is quick, certain and satisfactory.

Special commuted rates will be made for contract service to or from the stock exchange.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Dropped Dead from an Electric Light Wire.—How a Bogus News Despatch was Circulated.—False Report of Frederick A. Gower's Whereabouts.—Preparing to Abandon Pole Lines.—Electric Lighting in Orange.

THE fire which occurred at Wilson's tea store on Vesey street, January 20th, afforded a fresh opportunity for a crusade against overhead wires, and it certainly was a striking example of that imprudence which so frequently leads men to risk their lives in the most reckless manner. Frederick Simons, station-master from the Fulton street station near by, seeing that the wires of the United States Illuminating Co. were in the way of the firemen, ran up a ladder and, with his pliers, proceeded to cut them away, apparently without taking any precaution against the effect of the current with which the circuit was charged. As the wire was severed he fell to the ground and expired. There existed at the time a difference of opinion as to the cause of his death, some maintaining that he was killed by electricity, and others that his neck was broken by the fall. The surgeon who responded to the ambulance call said he was not killed by the fall.

The coal-handlers' strike caused some apprehension in electrical circles, as it was thought that a coal famine would certainly cripple the electric lighting companies. They were found to be pretty well supplied with fuel, however, and prepared to resort to all manner of expedients in order to keep up steam.

The critical state of affairs at Weehawken afforded an opportunity for a news agency operated by Dow, Jones & Co., to lay a trap for the discomfiture of the financial news bureau of J. J. Kiernan & Co. Two or three different despatches were sent from Weehawken to Dow, Jones & Co. by the Western Union lines, giving the status of affairs at the coal docks, followed by one announcing the beginning of a riot in which the police were overpowered by the strikers. This report, although entirely without foundation, appears to have been circulated at once through Kiernan's agency. Although every effort has been used to explain the affair, there is reason for believing that sufficient care is not exercised in guarding the sanctity of private telegrams.

Some time during last fall, the New York *World* published an article which stated that Frederick A. Gower, the electrician and amateur aeronaut, who was supposed to have been lost at sea while trying to cross the English Channel in July, 1885, from Dover to Calais, in his big balloon, was not dead, as had long been thought. The article asserted that Mr. Gower was living in luxury at Malabar Hill, Bombay. It was also intimated that there was a beautiful woman in the case. Melville Gower, a merchant of New Haven, an uncle of the missing man, upon seeing the article immediately wrote to Rev. Mr. Hume, an American missionary at Bombay, inclosing a photograph of Gower, and asking that he make a thorough inquiry and search for his relative. On January 19th, a letter was received from Mr. Hume. In it he stated that there was not the slightest foundation for the story as printed. The European settlement at Malabar Hill, Bombay, is so small, Mr. Hume says, that the coming and going of an English-speaking individual is something of more than ordinary importance, and is long remembered by the colony. The photograph of Frederick Gower was not recognized by any one in the colony.

Commendable progress is being made by different companies in preparing for the abandonment of their pole lines. During the past month cables have been drawn into the Broadway conduit of the Western Union Telegraph Co. The same company has also strung quite a large amount of cable on the elevated railway. The Metropolitan Telephone and Telegraph Co. has also placed cables in the Sixth avenue subway. The actual beginning of this work indicates that, if the money holds out, a large amount of subterranean construction may be looked for during the coming year.

A delegation of the city officials of Cleveland, O., consisting of mayor George W. Gardner: C. G. Fore, city engineer; H. H. Rebbeck, city electrician; David Monson, building inspector; and aldermen Herrman, Seigris and Carpenter, called at the mayor's office in the City Hall, January 22d, and were received by acting-mayor Beekman. They were here to examine the electric subway system.

The Citizen's Gas Light Co. of Orange, N. J., having been awarded the contract for illuminating the streets of that city for the next two years, have purchased a 50-light plant of the best workmanship, and complete in all details. Arrangemente have been made with P. B. Fairchild & Co., who are erecting a new building, about 30x48 feet, on the railroad, in the rear of their shop on Reock street. It will be two stories and basement, and

Digitized by Google

connected with their present building by a bridge. It is intended as an electrical station, from which light and power may be supplied from the new plant.

NEW YORK, Jan. 24, 1887.

PHILADELPHIA.

The Fire at the Temple Theatre.—National Electric Light Association.—The Edison Electric Light Co.—Stealing Aerial Cables.—A New Electric Company at Atlantic City.—Infringement Suit of the Edison Electric Light Co. Against the Westinghouse Co. at Trenton.—Permission of Underground Conduits by Councils.

AN investigation as to the cause of the recent disastrous fire at the Temple Theatre in this city, whereby two firemen lost their lives, is now in progress. The theatre is lighted by electricity, and it is thought by some persons connected with the establishment that the fire was caused by an electric light. But on the other hand, the electricians who have testified in the matter are just as positive to the contrary. Testimony was heard from William F. Connor, electrician at the Temple theatre, who said that he put up electric lights in Niblo's Garden, New York, and Francis P. Haggerty, assistant manager of the theatre, who made an effort to put out the fire in the booth. Mr. Connor said that the electric wires in the theatre were placed in the ordinary manner, care being taken to have them perfectly safe. He thought the lights were at a safe distance from the paintings and drapery, and could not see how the fire could have originated from this cause. The theatre was lighted by the Edison system, the local agents being Hicks, Walker & Keppler. They denied the possibility of a fire as the result of the use of the Edison system. "If there was bad wiring," said Mr. Hicks, "that might account for it. Bad wiring in any system might cause a fire. But as for any drapery, or any material not extraordinarily inflammable, being ignited by contact with one of those globes, it is impossible." Mr. Keppler demonstrated by putting his handkerchief on top of a globe, inside of which the carbon film was burning. The cambric gave forth what at first looked like smoke, but what the reporter concluded was steam when it ceased to arise. After five minutes the handkerchief was taken off without a singe.

The whole subject of danger from the globes is so utterly new that J. A. Fowler, editor of the *Exchange and Review*, could find no literature bearing on the subject after a reporter who had vainly searched the Mercantile and Philadelphia libraries for information on the subject, applied to him. "It is safe to say," said Mr. Fowler, "that if the Temple theatre was set on fire by an incandescent globe it is apparently the first case on record. As far as we know the carbon film can not bring the glass globe surrounding it to a greater heat than 150° Fahrenheit, and even decayed wood requires 300 for ignition."

In compliance with a call issued by chairman A. J. DeCamp, the executive committee of the National Electric Light Association met a few days ago in parlor C of the Hotel Lafayette, to make arrangements for the third annual meeting of the association. The following gentlemen were present at the meeting:

A. J. DeCamp, of Philadelphia, chairman; Frank Ridlon, of Boston; Dr. Otto Moses, New York; James T. Lynch, New York; Clarence E. Stump of the *Electrical World*, New York; Arthur Steuart, Baltimore; George W. Boyer, Philadelphia; Thomas McCoubray, Jr., and J. L. Morrison, of Baltimore.

The convention will be held either in Horticultural Hall or the Union League Annex, on Tuesday, February 15th, next, but the headquarters will be at the Hotel Lafayette. There will be nearly 300 delegates present, among whom will be Dr. Duncan, Professor Roland, Professor Thurston, and Professor Brackett.

At a meeting of the Edison Electric Light Co. recently, it was determined to increase its capital to $1,000,000. Subscriptions were received by B. K. Jamison, Charles M. Swain and Samuel B. Huey, up to the 15th of the present month, on which date the stock was allotted among the subscribers, the committee reserving the right to divide the stock in such manner as should, in its judgment, best promote the success of the company. Temporary accommodations for the company have been secured at 108 South Fourth street, until the new Fourth street National Bank building is completed, when it will remove to that building.

A few days ago the discovery was made at the central office of the Bell Telephone Co., at Fourth and Chestnut streets, that a number of the wires were "open." An investigation showed that three of the company's cables extending over the house tops along the north side of Chestnut street had been cut between the supports on the American Hotel and the *Bulletin* office. The cutting, it is said, was done about 5.20 o'clock. Each of the cables contains 100 wires, which are insulated and covered with lead piping. Two of these cables, in all 400 feet, were stolen, the third being left behind. The wires were in working order at business hours yesterday morning.

The Atlantic City Underground Telegraph, Telephone and Electric Light Co. has been organized at Atlantic City, with George Allen, Dr. T. K. Reed, Charles Evans, Charles McGlade, John B. Champion, S. R. Morse, Daniel Morris and James A. O'Reilly as incorporators. An ordinance granting them the right of way to lay conduits has passed first reading in city councils.

The Edison Electric Light Co., of New York, has begun in the United States Circuit Court at Trenton, eleven separate suits against Westinghouse, Church, Kerr & Co., of East Orange, N. J., representing the Westinghouse Electric Co., of Pittsburg, Pa., for alleged infringement of patents covering the system of incandescent electric lighting. Injunctions and orders requiring accounting to be made by the defendants are asked for.

The Philadelphia Time Telegraph Co. has been authorized by councils to lay wires to furnish standard time. An ordinance giving the Bell Telephone Co. permission to lay conduits and erect poles on a number of streets in the central part of the city was also adopted by councils.

PHILADELPHIA, January 17th, 1887.

BOSTON.

The Boston Police Signals.—Electric Lighting in Official City Reports.—Consolidation of Electric Lighting Interests.—Pinkham's Patent on Electric Gas Lighting Sustained.—The Government Telephone Suit Re-commenced in Boston.—Preparations of the Counsel of the American Bell Telephone Co. for the Supreme Court at Washington.—Lectures on Harnessed Lightning.

THE refusal of the city government to honor bills contracted for the police signal system has led the board of police to appeal to the legislature for authority to introduce in the city proper such a system as is now in use in South Boston. This will probably settle definitely the question of the board's power to introduce such measures as it shall deem best for the interests of the police department. The board claims that the system is a public necessity, and will seek to maintain its position before the legislature.

The fire alarm department is placing boxes upon each floor of the city hall, to be used in case of fire. The boxes are about three by four inches in size, with glass front, the glass to be broken and the button inside to be pushed in case of fire.

An exhibition of the Rogers' system of auxiliary fire alarms was given at City Hall yesterday afternoon. By this system, rooms and buildings distant from the alarm boxes are connected with the boxes, and an alarm can be sounded without going to the box.

The reports of the mayors of different cities frequently contain matter relative to electrical apparatus. The mayor of Boston gives the following concerning electric lighting:

The report from the lamp department includes these statistics: Number of lamps of all kinds in use in the city of Boston on Jan. 1st, 1886—Gas, 9,978; oil, 2,630; electrics, 446; large gas lamps, 63; total, 13,117. On the first of January, 1887, the number was, viz.—Gas, 10,057; oil, 2,785; electrics, 494; large gas lamps, 59; total, 13,395; increase, 278.

The increase of the separate sections of the city has been as follows: Roxbury, 28; West Roxbury, 78; Dorchester, 105; South Boston, 26; East Boston, 23; Charlestown, 3; Brighton, 20. The number of gas and oil lamps put up during the past year was 367. The number of oil lamps changed to gas lamps was 29.

Electric Lights: Jan. 1st, 1883, 114; Jan. 1st, 1883, 381; Jan. 1st, 1885, 401; Jan. 1st, 1886, 446; Jan. 1st, 1887, 494; increase during past year, 48.

The location of the electric lights is shown below:

	1885.	1886
Brush, city proper	195	206
" Roxbury	38	47
" Dorchester	5	5
N. E. Weston, city proper	55	60
" South Boston	69	74
" Charlestown	26	38
Merchants' city proper	25	27
Citizens, East Boston	33	37
	446	494

The mayor of New Bedford, characterizes the electric lights "as an expensive luxury." Perhaps his honor is a protectionist, and would like a heavy tariff put on electric lighting, in order that the wharves of his town might once more be weighed down with barrels of whale oil.

The rumors which have been going the rounds for some time, of consolidation of electric light companies and gas companies, have become true so far as the electric companies are concerned, but not true in regard to the gas companies. The Brush Electric Light Co and the Merchants' Electric Light and Power Co. have consolidated under the name of the Boston Electric Light Co. with headquarters in Rogers' building.

The officers of the new company are as follows: President, Fred. Gilbert, formerly of the Merchants' company; vice-president, Hugh O'Brien, formerly treasurer of the Brush company; treasurer, Samuel S. Sias, formerly of the Brush company; superintendent, Patrick Fay, who has been the efficient superintendent of the Brush company for several years. It is expected that the Weston Electric Light Co. will soon be merged with the others,

Digitized by Google

thus giving the new organization a monopoly of the electric lighting business of the city.

Judge Colt, of the United States Circuit Court, has sent down an opinion in the case of the Boston Electric Co. *vs.* Charles E. Fuller, in which he orders a decree for complainant. This was a suit brought for the infringement of a patent granted July 27th, 1880, to George F. Pinkham, assignee of Jacob P. Tirrell. The invention relates to apparatus for lighting gas by electricity, in which the gas-cock is opened and closed by electric action upon a mechanical device connecting with the cock and a battery. The court finds that "the patent covers an important improvement in the art of lighting gas by electricity, and it should receive a reasonably broad construction, and those should be held to be infringers who accomplish the same result by substantially the same or equivalent means." The defendant's apparatus, the court finds, is the same in principle as the plaintiff's, though its construction differs somewhat from the plaintiff's. J. E. Abbott for complainant; E. P. Payson for defendant.

In the case of the Electric Gas Lighting Company *vs.* the Boston Electric Company, which was a cross action against substantially the same parties as were plaintiffs in the above action, of the Boston Electric Company *vs.* Fuller *et al.*, the bill is dismissed by Judge Colt. E. P. Payson for complainant, and J. E. Abbott for defendant.

The long expected bill in equity brought by the United States against the American Bell Telephone Company, in which it is sought to annul the Bell patent, was filed on the 13th inst., in the United States Circuit Court, and is the same, in all essential particulars, as that filed in the Circuit Court at Columbus, Ohio. The attorneys for the American Bell Telephone Co. are busy at work on their papers for the Supreme Court at Washington. Their arguments will be illustrated by charts showing in diagrams the various infringing instruments and all of the points where an appeal to the eye can aid the appeal to the ear. They will have a battery of 1,000 cells with which to illustrate the actual instruments, and perform the experiments necessary to show up the matters at issue. This style of argument, an appeal to the eyes of the court by operating the instruments and illustrating by apparatus the principles at stake, was very effective in the New Orleans case. The "opposition" also "performed," but it was like the trial of skill between Moses and the magicians before Pharaoh. Mr. Storrow's snake swallowed those of Mr. Beckwith, easily. There is great interest in this trial, so much so, that admittance will be by card. Justices Mathews and Blatchford of the Supreme Court have already decided in favor of the Bell company, in the circuit courts—in some of the cases now before them.

The interests at stake are enormous, and the evidence must necessarily be of a most convincing character, for the court to reverse the uniform decisions of the circuit courts, and to disturb such vast vested interests. The Bell stock is held very strong at present, and shows evidence of advancing in price.

A lecture on "Harnessed Lightning" was given at Tremont Temple, on the evening of the 12th inst., by Mr. George H. Hartwell. The platform was covered with electrical apparatus, and electric lights, arc and incandescent, and an electric railroad were shown, and a sewing machine, coffee mill, pump, a lathe, and other machines were operated by electric motors, the current being obtained from dynamos and storage batteries on the stage. Mr. Hartwell thoroughly explained the workings of the different systems of power and of the arc and incandescent lamps. He also showed the methods of isolated and central station lighting, as well as street lighting. Describing motors, he explained the manner of carrying the current and its easy control by the operator. He claimed the electric railway as a means of rapid transit of the future, and explained the various systems of street railways now in use.

BOSTON, January 16th, 1887.

CHICAGO.

Winter Sports.—Explosion in an Underground Conduit.—Iowa State Firemen's Association.—Electric Lighting Notes.

WE are having a rage of blankets and moccasins, toboggans and snow-slides, lighted by electric lamps, and the girls, dressed up like Scotch fishwives or "bois brulé" Frenchwomen, are happy. There is an exhilaration in going down a steep hill at 25 to 30 miles an hour, when the girlie knows that her best fellow guides the toboggan, and a great, burly policeman stands at the bottom of the slide to stop the blessed thing from going through the fence into the next county; and the boys seem to enjoy it as well as the girls. But it is debateable whether there is any more fun in this kind of thing than there used to be, to us who are now gray-headed, when we neither tobogganed in Indian blankets, nor even "coasted." We simply "slid down hill," sometimes on a shovel, often on a barrel stave, and occasionally on an old chair-frame with a board or stave woven through it to make a runner—yes, or on a chopping-bowl. We had sleds, but these other luxuries the sliders of to-day know little of. It was work, but there was fun in it.

Every now and again some Jack-in-the-box is sprung upon the public with the statement that the Chicago underground system is a failure. These stories come, not from those who know, but from those who hope that the underground idea shall prove impracticable.

There was a fearful explosion here the other day, which at first had an ugly look for the conduit company. Investigation showed a bad leak from the gas main, near an iron pipe running across Lasalle street, into the area of the block opposite the Grand Pacific. Through this pipe are wires leading into the buildings, and into these same buildings the conduit company have their laterals, the ends of which were open. The areas and cellars filled from the gas which followed along the iron pipe, and the pressure forced more or less gas into the conduit through the open ducts. Had these ducts been closed—they should have been—no trouble would have arisen with the conduit; some other fellow would have done the walking. The gas was ignited in the area while parties were searching for the leak. They found it, and the man-hole cover in front of the board of trade was blown into fragments, one of which sailed upward, dove through the window of the trading-room, and scared everybody generally, but did little other injury. One gentleman was cut by flying glass, and, while this is not serious, the injury will leave a reminder in the shape of an ugly scar. The chunk of iron has been duly labeled and placed in the secretary's museum, and the conduit company, now that the horse is stolen, will proceed at once to fill all the open ends of the pipes, to prevent similar occurrences in the future.

The fire-worshippers in Iowa have two annual gatherings, one of a purely business character, while the other is a sort of business jollification—the former a winter gathering, the latter a summer tournament. The winter gathering of the organization—the State Firemen's Association—met at Des Moines on the 12th. In addition to other matters of a business nature, the following resolution was introduced by Mr. A. Christy, of Des Moines, and passed:

"*Resolved*, That we, the members of the Iowa State Firemen's Association, in convention assembled, do most cheerfully and heartily recommend to the different fire departments of the state the Gamewell Fire Alarm as the most efficient and effective system now in use, and would respectfully call the attention of the city councils of Iowa to this fact, that they may inspect the workings of the same."

The Palmer House has recently been re-wired for both incandescent and arc circuits by the United States company. The Leland has been done in the same manner by the Sperry company. The Fort Wayne Jenny people have just put in a 60-arc light plant for the Armour Packing Co. at St. Louis, and an addition of 16 lights at Lassig's Bridge Works here. The Electrical Supply Co. have recently installed an arc 60-light plant at St. Charles, Mo., of the Excelsior pattern. The same company is wiring the capitol at Springfield, Ill. The Mather-Perkins general agent here, Mr. J. H. Reid, recently closed contracts for the lighting of the Hennepin avenue theatre, at Minneapolis—700 incandescent lights—and the Oliver Wendell Holmes Hospital, at Hudson, Wis. The Edison people have in hand, nearly ready for delivery, the following plants: Deming & Durkee, O. D. Wetherell, W. W. Kimball, Anglo-American Packing Co. works, Phœnix Insurance building, and Grace Hotel.

The Edison company has been housed in uncomfortable quarters for some time, until now. Their offices were upon the ground floor, beneath which the engine and dynamo fumed and pounded and sang, more or less, and heated the office unduly, while interfering with both comfort and conversation. The offices have been removed into comfortable, airy and light quarters above stairs, in the same building, and the countenances of all the officers of the company are radiant with glee thereat.

CHICAGO, Jan. 15, 1877.

SAN FRANCISCO.

The Postal Telegraph Co. Nearly Ready for Business.—Appointments in its Service.—District Messenger Service.—Underground Conduit Franchises Sought in San Francisco.

EVENTS are thickening in telegraphic circles. Mackay's Postal is no delusion, it is a *fait accompli*, and by the 1st of February is expected to be open to accommodate the public. Never did a rival to the great monopoly start under better auspices, with some glaring exceptions. These exceptions, to be alluded to hereafter, relate to features of management that have proven fatal to many an enterprise of the same kind.

For the past eleven years the Western Union have enjoyed a complete monopoly of this coast, and to their credit be it said, they have not been so exacting, in view of their complete control, as has been the case with railway monopolies. The overland service will not be much improved even with a rival in the field, for it is now good; hence if any improvement is made by rivalry, it will be in local business. It is true that customers have been kept waiting in strings of from 20 to 30—like voters at a polling place—between the hours of 5.30 and 6.30 P. M. because of only *one receiver* being on duty to accommodate them, and the fault, in a measure, is as much that of the customer, as

Digitized by Google

that of the company, because they keep their messages in their pockets until they are on their way home; but when a rival is across the way the Western Union must recognize the necessity of meeting the public, or abide the consequences.

It will be a long time before "the Postal" will be able to accommodate the public as the Western Union can do at present. It may make an attempt to bid for Eastern business, and may, in some cases, render satisfaction; but, in all fairness, their success in that direction may be doubted. With a knowledge of the country through which they pass, one need be no prophet to forecast that many a time before May 15, 1887, their customers will be notified "wires down." Half a dozen notices like this, will dull the "edge of public good will," and the exigencies of business will compel merchants to patronize the Western Union, no matter how much they would like to help the young rival.

One of the exceptions to the favorable auspices of the new company, alluded to above, is to be found in injudicious appointments in the management. Mr. Hosmer, of Canada, appoints an old friend of his as manager of the San Francisco office, who is totally unknown to the public and unacquainted with the public temper and necessities. Mr. Mackay and Mr. Rosener are, of course, publicly well-known, but half the business people do not know those gentlemen by sight; hence they will only know the company through the men with whom they are brought directly in contact. Mr. Laven has been on this coast only two years, and most of that time was in an operating room, or on Oakland wharf as operator in the train despatcher's office. Personally Mr Laven has many well-wishers, and it is to be hoped that he will disappoint his enemies, but speaking for the good of the telegraphic fraternity, and with a desire to see the Postal come to stay, it seems fair to say a better selection might have been made for the chief office on the coast. John Leatch, another Canadian, but an old timer on this coast, is to be chief operator, John is as fine a fellow as ever entered an operating room, but rather ante-deluvian in his ideas and methods.

Oakland is the greatest field for local competition, and it behooved the Postal to put "live men" in such a place, but it appears that Mr. Hatch—a man who has been laughed out of every office on the coast—is to be manager there. Such appointments seem attributable to "influence" more than to sound judgment. The Postal, have entered into a contract with the San Francisco District Telegraph Co. to deliver their city business under the management of J. B. Gill. If Mr. Gill will devote his entire attention to this department, it will doubtless be satisfactorily run, but if he leaves it to his smart boys, John Barry (the manager of the Western Union Delivery Department, a man who does not need a directory for two-thirds of his business), need not be afraid of losing his well earned and deserved laurels.

The messenger boys of both the District companies have been on a strike for the past week, with no signs of a compromise. The boys demand 75 cents per day. The companies have been paying them 5 cents per message. The companies charge 30 cents per hour for the boys' time, and a boy is allowed to take only one message at a time; hence the boy receives 5 cents and the company 25 cents for the boy's service. Of course, half hour messages are 15 cents, but the companies gain on the boys' time without incurring any expense save the placing of boxes. Now, in view of the fact, that a boy is compelled to pay $18 to a tailor for a very inferior uniform, $1.25 for a cap, and $2.50 at least every six weeks for shoes, and is subjected to a diabolical attempt at discipline by *fines*, for trivial offenses, imposed by "fresh" boys (no older than themselves) who happen to be behind the counter, one may consider the claim of the boys to be well founded. Many corporations draw the reins too tight. Nothing is so conducive to dishonesty in a boy as the feeling that he is unfairly dealt with.

There is a great demand just now for franchises to lay underground conduits; Geo. S. Ladd, representing one company, and a Mr. McGrew another. The board of supervisors have laid the matter over for future consideration, or for the consideration of their successors, unless their palms are greased. As their successors come into power Monday, January 3d, and like all boards they will profess to be saints on entering office—but probably exit sinners—it behooves those desiring the franchise to put their hands in their pockets. The present board can only hold another meeting.

"'Tis a wicked world my masters."

San Francisco, Dec. 21, 1886.

Taking up the thread of the letter of December 21st, in regard to the Postal Telegraph Co., there seems to be no reason to change the opinion expressed as to the management, except that credit should be given for the selection of some able men for subordinate positions. They have induced Thomas H. Berry to resign the chief operatorship of the Western Union at Sacramento to accept a night chiefship with them in San Francisco. The reason for this is obvious. Berry is the only man on this coast of commanding ability as an electrician, practical wireman, and one of the best operators, who would change without greater lucrative inducements being offered; but some of the knowing ones declare that Berry will receive a private *bonus* from the manager and chief operator, as without him they would apparently have to send east for a man to put up a duplex, "quad," or even a set of Milliken repeaters.

That the change may prove advantageous to Mr. Berry is the heartfelt wish of all the fraternity. Ben. C. Shearer, traffic chief of the Western Union at San Francisco is going across the way even at a less salary, while many of the best operators are going over at the same wages—$90 per month.

There must be something radically wrong when men will seek

> "Among strangers to find
> That repose, which at home
> They had sighed for in vain;"

or, in other words, better treatment. If the Postal Telegraph Company will fill their eastern offices with as good operators as they have here, the public may look for good service.

It is a pity, however, to see a man of Mr. Mackay's generous nature imposed on by incompetence. Many stories about the shocking manner in which the line was constructed have been heard. They have been regarded as possibly due to prejudice of rival builders; but a personal inspection of the line, as far as Port Costa, over the hills (it is on hills and side hills where the experienced line builder shows his "craft"), discloses a very bad job, notwithstanding the use of the best material; braces on the wrong side, and in many cases the pole bent with the strain. When the rainy season is past the evil of this lack of experience will manifest itself to Mr. Mackay's extra cost, and it is a pity, as he furnished *carte blanche* for expenses.

The board of trade of Los Angeles have got their ire aroused at the Western Union, because the Western Union, with a total disregard for public convenience, moved their main office to an out of the way place to reduce office rent. Their resolutions of condemnation, and liberal inducements to Mr. Mackay to run his wires to that city, were telegraphed broadcast. Mr. Jaynes has been in Los Angeles for some time adjusting and remedying this evil, and when he returns it is to be hoped he will be imbued with the necessity of putting new life into the Los Angeles management, which will keep pace with the growth and prosperity of that thriving city. It is second only to San Francisco in California, and third on this coast. The Western Union ought to "pension" Mr. Haines, or consign him to the editorship of his *Temperance Gazette*, where it is to be hoped he will be of more benefit than as the manager of Los Angeles' office.

There are a great number of aspirants to succeed Mr. Berry at Sacramento. The place was offered to Mr. B. C. Shearer, but he declined it to go to the Postal at less salary; that, however, does not deter J. E. Morris (the "beau brummel" of the Oakland ferryboats); Ed. Flanagan, assistant chief at Ogden, and John F. Allen, present night chief at Sacramento, and *ci devant* manager of that office. If any man is deserving of that office John F. Allen is, for his persistency and stubborn resolve command admiration. Many remember his endurance and pluck during the *strike* of 1883, when he never missed a night, and always put in his 12 hours during those 24 days.

It is to be hoped that the place will not be filled by bringing from the east some overworked man, broken in health and strength through the confinement and toil of an operating room and ready for any change, to serve his same hard masters here till he breaks down altogether, and is turned off to shift as best he can—perhaps to be cared for and at last buried by his fellow-craftsmen, like poor Moreland and others now at rest in the Odd Fellows' cemetery.

The old board of supervisors has given place to the new without granting franchises to any underground conduit company. Mayor Pond is opposed to wires being strung on poles through the city, as is also the chief engineer of the fire department, and it may be presumed Mr. Ladd will, at an early date, be granted a conduit franchise, and that an ordinance will be passed compelling all telegraph, telephone and electric light companies to use underground conduits.

The Western Union are stringing a copper wire from here to Ogden. This will be of incalculable benefit to them, as they have no wire that will "quad" to Ogden at present. The Postal, it was said, were also to string a copper wire; but so far they have only two No. 6 gauge iron wires on their poles. What they will do in the near future is a mere conjecture, but in some quarters the opinion is that they will "sell out."

San Francisco, Jan. 5, 1887.

LITERATURE.

REVIEWS.

The Electric Motor, and its Applications, by Thomas Commerford Martin and Joseph Wetzler. (With 200 illustrations.) New York: W. J. Johnston, 1887.

It is indeed a pleasant surprise to find, among the great number of recent works upon electrical subjects, one containing so much real information as this book, and information, too, which

Digitized by Google

is new and valuable. We have been thoroughly interested in reading the work, and have found it a comprehensive and thoroughly practical treatise upon the general subject with which it deals, and especially upon the subject of electric railways. Notwithstanding the extent of the popular interest which has been developed in this latter subject during the last three or four years, there is still a great dearth of popular knowledge relative thereto. That electricity may in some way be employed as the power for driving vehicles, is generally recognized, but in what particular manner it can be applied is, in the minds of the general public, very vague. A work such as this, therefore, giving in concise language and in terms not too technical, descriptions of the necessities, the experiments, and the realizations of electric motors and electric railways, will be cordially received and appreciated.

Without devoting too much attention to the consideration of elementary features, brief descriptions are given of the typical early motors, commencing with the experiments of Jacobi in driving a boat upon the Neva in 1838, and those of the Vermont blacksmith, Thomas Davenport, who, in 1833, instead of buying a stock of iron, invested his money in the electro-magnet, which led to his building an electric motor in 1837. These matters are followed by a few pages of more or less technical and theoretical consideration of the electrical transmission of power, after which comes the most important part of the book, namely, that treating of the modern electric railway. Those who have not familiarized themselves with the modern applications of electricity will be surprised upon learning to how great an extent the electric railway is already in practical use. The authors have been fortunate in securing descriptions of the very latest forms of motors, and of actual and proposed systems, thus rendering the work very complete to the present date.

The industrial applications of electric motors, as well as marine and aerial navigation, are other interesting topics receiving due consideration.

A word of commendation must be added for the attractive appearance bestowed upon the volume by the publisher, and for the abundance and quality of the illustrations.

PERIODICALS.

The American Railroad Journal and *Van Nostrand's Engineering Magazine*, have been united, appearing for January as *The Railroad and Engineering Journal*, in very handsome form, and with a variety of interesting contents, embracing the leading features of both its predecessors. Mr. N. M. Forney, having purchased the business of both publications, conducts the new journal as editor and proprietor. The January number gives a brief history of its progenitors, illustrated by a fac-simile of the title of the initial number of the *Railroad Journal*, January, 1832; the latter embellished with a woodcut of a locomotive and train of cars of the period. A wide range of subjects is treated, and the number is copiously illustrated. Readers of both earlier journals will find interest in the new journal of Mr. Forney.

CATALOGUES AND PAMPHLETS RECEIVED.

The Ball Electric Light Co. send us an extremely tasteful circular, daintily illustrated, setting forth a variety of electric lighting machinery and lamps supplied by them, with many testimonials to the efficiency of their system.

The Fuel-Gas and Electrical Engineering Co., limited, and the Westinghouse Electric Co., both of Pittsburg, Pa., issue a pamphlet of 77 pages, embracing forms of agreements, and other information, bearing upon the joint or separate introduction of the fuel-gas appliances of the former company and the electric lighting system of the latter company. The introductory matter comprises some account of the systems and appliances of both companies, of much interest to gas and electric light companies, as well as to the public. The forms of agreement given, contemplate exclusive licenses for the use of the patented appliances of either company, as well as licenses not exclusive.

The Vitrite and Luminoid Co. send us a sheet embracing a list of their patented fittings for incandescent lights, with uncommonly effective illustrations of the articles offered by them.

The Sprague Electric Railway and Motor Co.'s Catalogue "A."—Stationary Motors—is really a luxurious quarto pamphlet, of 45 pages. It includes some preliminary discussion of the problem of electric transmission of power, a brief account of the Sprague motor, and copies of actual records of the performance of some ten motors in use by purchasers for various purposes, making a very good exhibit. There is also included a list of the motors built by the Sprague company with their present location and occupation when known, accounting for 225 machines issued, Nos. 226-230 in stock, and Nos. 231-290 in course of construction.

We have received from the Van Depoele Electric Manufacturing Co., Chicago, a well illustrated pamphlet describing the Van Depoele system of electric railways, with an account of a number of successful introductions of electric traction by the company in several cities and towns in this country and Canada. The Van Depoele company has assumed a leading position in this growing branch of electrical application.

C. N. Caspar, Bookseller and Publisher, Milwaukee, Wis., issues a prospectus of a General Directory of the American Book, News and Stationery Trade and kindred branches.

Third Report of the Board of Commissioners of Electrical Subways of the City of Brooklyn, dated December 16th, 1886.

Messrs. Partrick and Carter send us their Catalogue of Electrical Supplies for 1887, embracing a very complete list of general electrical machinery and material.

ELECTRICAL NEWS AND NOTES.

EXAMINATION IN ELECTRICAL MEASUREMENTS.

COURSE IN ELECTRICAL ENGINEERING, CORNELL UNIVERSITY, ITHACA, N. Y.,—FALL TERM, 1886.

1. Define the ohm; the ampere; the volt. Also the legal ohm, ampere, and volt.

2. Describe briefly the method used by the British Association committee, and afterward by Lord Rayleigh, for determining the true value of the ohm. Show what quantities must be observed.

3. Describe and demonstrate Cary Foster's method of comparing resistances by means of the divided metre bridge. Show how this may be applied to calibrate the bridge wire and determine its resistance per unit length.

4. In determining H by means of the Kew magnetometer, show how the length of the deflecting magnet is eliminated, and explain the corrections for temperature and induction.

5. Deduce the expression for the potential due to a magnetic shell, and reduce to simplest form involving linear quantities, for a shell with a circular edge, for a point on the axis of the circle. Also find the expression for the force in the direction of the axis on a unit pole.

6. What is the advantage of the Helmholtz over the single coil tangent galvanometer? Why is the distance between coils made equal to their radius? Describe the "Vienna method" of measuring currents.

7. Describe briefly the two forms of Ayrton and Perry ammeters. State their advantages and disadvantages. Describe the Siemens ammeter (dynamometer form).

8 How can potentials be measured in legal volts? Describe some of the portable voltmeters. How does temperature affect their indications? Why?

9. What can you say of the use of cells as standards of difference of potential? Give briefly the method pursued by Lord Rayleigh to determine the E. M. F. of Clark's cells.

10. How is the influence of errors of observation on a result to be determined? Explain the bearing of this upon the number of places of significant figures to be retained. Apply to the case of the measurement of current by a tangent galvanometer and suppose deflections can be read only to tenths of a degree.

THE TELEPHONE CASE IN THE SUPREME COURT.

A JUNK SHOP MISSILE.

The N. Y. *Times* publishes a Washington telegram headed: "A bombshell for Bell. Startling charges in the telephone cases. Four 'revelations' in the Hill brief filed with the Supreme Court in Washington." This startling piece of news consists of certain oft-repeated charges that Prof. Bell obtained some part of his telephone invention from a surreptitious inspection of Gray's caveat, to which he was given access by examiner Wilber. People's memories are commonly very short when applied to facts that do not immediately concern their own interests. It may be worth while, therefore, to remind the public that Prof. Gray, in a lecture delivered at Chicago, early in the year 1876, awarded the discovery of the telephone, so far as it had then proceeded—and this was after his own caveat had been filed—to Mr. Alexander Graham Bell; that this public acknowledgment was reported by the Associated Press in the leading papers in the United States the next day; that this newspaper report was clipped out by Prof. Gray, and sent by him to Prof. Bell, with a letter appropriate to such an act of magnanimity, which letter has been exhibited in court more than once since that time. How "startling" the present revelation ought to be, we can only infer from this remarkable antecedent fact.—*Evening Post.*

POLARIZATION OF RESISTANCE COILS.

Dr. B. F. Thomas, State University, Columbus, Ohio, has the following interesting note in *Science*, for January 7.

In August last Professor Mendenhall in conversation with the writer, alluded to his observation of the polarization of certain resistance coils, and suggested an examination of the coils in this laboratory. The examination was made and the results stated in remarks upon Professor Mendenhall's paper at the Buffalo meeting of the American association. A brief account may not be without interest and value.

The idea entertained by Professor Mendenhall at the time seemed to be that the polarization was of a "statical" nature; the deflection obtained on connecting the coil, through which a current had been passed, with a galvanometer, being produced by the "residual charge." The examination of our coils was undertaken with the same idea, the "condenser discharge" method being made use of, substituting the coil under trial for the condenser. The galvanometer was a 6,000 ohm astatic Thomson, by Elliott Brothers, its needle making a vibration in about ten seconds. A Fuller cell and Sabine discharge key were used. Polarization was found in every coil in the laboratory, except in a standard B. A. unit from Elliott Brothers. It was also found in a Hartmann box loaned for examination by Messrs. Queen & Co. The effect was found to vary widely in different coils in the same box, particularly so in a box of 100,000 units from Elliott's, whose 40,000 coil gave 40 degrees deflection against six or seven degrees for any other coil in the box. On opening the box, it was found that the 40,000 coil had been heated till the paraffine had melted and some of it had run off, while the other coils were well covered, as usual in Elliott coils. The Hartmann box, whose coils were not paraffined, showed the effect more strongly than any except the 40,000 Elliott. It was observed that the coil terminal connected to the positive pole of the battery in charging, was itself positive in discharging; that reversing the battery reversed the discharge deflection; that the deflection was not momentary, as with condensers, but that it indicated a steady current, diminishing slowly, but not ceasing in some instances after eight or ten hours; that when the coil was charged by battery for several minutes, and then the current reversed and allowed to flow a few minutes longer, the discharge current was at first due to the last charging current, but after a time it ceased, and was followed by another discharge current due to the first charging. An experimental coil was then made up of 1,800 ohms of wire having unparaffined cotton insulation. It was wound on a warm rainy day, and tested immediately, showing the strongest polarization found, driving the spot of light violently off the scale. The coil was then baked in a hot air oven at 150° C. for an hour, and tested again when cool. No trace of polarization could then be found though the charging current was increased. The previous observations, of course, indicated electrolytic polarization as the disturbing cause; and the last showed, that, in the case of that coil, it was electrolysis of water absorbed from the air by the cotton insulation. The experimental coil was then heated, and soaked well with pure paraffine, and drained while hot until it seemed to be as nearly as possible in the same condition as the 40,000 Elliott coil, and tested when cool. No trace of polarization was shown. It was then put aside in the instrument case to see whether it could still absorb water enough to polarize. Ten days later, just after the Buffalo meeting, the coil was tested again and polarized strongly. On heating it again, the polarization entirely disappeared. A drop of hydrant water placed on the coil caused polarization to reappear in five seconds, and in five minutes the effect was so strong as to drive the needle to its stops.

The degree of error in measurement resulting from polarization was not examined, but Professor Mendenhall's statements show that it may be a considerable quantity.

It is obvious that unparaffined coils are, on this account, unsuited to the best work; also that coils well paraffined (as in the B. A. unit coil) or coils freshly baked and paraffined are free from such error.

The paraffining of ordinary coils, even when as thoroughly done as by the Elliotts, is not a permanent protection, probably because of cracking of the mass of paraffine, allowing vapor to reach the wire and insulation. A test will quickly determine the condition of any particular coil. A box might be made proof against polarization by filling entirely the space about the freshly baked coils with pure paraffine, just warm enough to flow freely. Temperature difficulties could be in part overcome by thermo-junctions, as in standards. Another, and on some accounts better plan would be to mount the coils in an impervious box with liquid-tight joints, and filling the interior with a petroleum oil, which may readily be found in market of such quality as to exhibit no polarization. With such a box, there need be no uncertainty as to the temperature of the coils.

A LEGAL BUREAU FOR THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

At the Detroit meeting of the National Electric Light Association a paper was presented by Mr. Arthur Steuart upon the importance to all persons engaged in the electric lighting business of a means through which they could learn at a moderate cost the status of any patent upon apparatus which they are called upon or compelled to use, and it was pointed out that if the members of the association knew the exact status of the various patents relative to electric lighting apparatus they would save a large percentage of their present expenses.

The executive committee of the association have considered how best to accomplish this result. To do it thoroughly would entail a cost which, while they believe the members would be amply compensated for the outlay, they still feel themselves constrained not to impose upon them at this stage. The bureau has been organized, however, on the basis that each member himself bear the cost of the investigations made for him, leaving the future to determine whether the members will prefer this method or pay each an annual tax for the support of the bureau. The advantage of the latter method would be that the tax upon each member would be small, and there would be no restraint put upon them in making use of the department.

The following is the official announcement of the executive committee:

PHILADELPHIA, Pa., Dec. 27, 1886.

To the Members of the National Electric Light Association:

Pursuant to the resolution passed at the August meeting of the association at Detroit, a legal department to the bureau of statistics has been organized, and the use of it is now offered to the members. The executive committee have placed this department in the hands of Mr. Arthur Steuart, of Baltimore, and feel confident in recommending him as a gentleman of integrity and ability to the association.

OBJECT OF LEGAL DEPARTMENT.

The legal department is provided for the purpose of giving the members an opportunity of having:

1st. Their patents.

2d. Those under which they are licensees.

3d. Those upon which suit is threatened against them. And

4th. Those presented to them for investment; examined by a competent patent lawyer and passed upon at the minimum cost.

PLAN OF WORK.

The method of work will be as follows:

When a patent is submitted to the general counsel for examination, he will himself, or by competent agent, make a thorough examination of all American and foreign patents, upon the same subject, as well as other sources of information available for this purpose, and prepare as elaborate an opinion as may be necessary with reference to the validity, scope and freedom from infringement of the patent. This opinion when prepared will be submitted to a committee consisting of the custodian of the bureau of statistics, and such other persons as may be designated by the executive committee, who will consider it with the general counsel, and certify their conclusions to the member making the inquiry. This opinion will be filed and will become a part of the record of the bureau.

CHARGES.

All work done by the department must be paid for by the member ordering it.

In consequence of the varied character of the work it is impossible to fix any scale of prices, so that the members are requested to arrange with the counsel the matter of charges before work is begun.

In the event of any question arising with reference to the amount to be paid for any particular piece of work, the matter can be referred to the executive committee, whose decision will be binding upon both member and counsel.

For the convenience of members, it is stated that Mr. Steuart has an office in Washington, at No. 605 Seventh street; in Baltimore, at No. 213 East German street, and in New York, at No. 137 Broadway; so that if consultation with him is desired, it can be had in the place most convenient to the member, by appointment. All communications by mail should be addressed to Baltimore.

ANOTHER NEW APPLICATION OF ELECTRICITY.

It is stated in a French paper that Prof. Place, of the Cavalry School of Saumur, has recently applied electricity with great success to horses which prove refractory while being shod. A vicious beast will often give much trouble in shoeing. M. Place's method renders it at once tractable, and permanently cures its aversion to the forge. An electric shock is given through a bridle of special form.

THE LIGHT FROM COAL.

One pound of coal, according to recent Franklin Institute tests, will yield an amount of light averaging 150 candles per hour with the electric arc light (about 60 per cent. of this if glass shades are used), 20 candles with incandescent lamps, and 14 to 17 candles with gas. In this estimate it is assumed that steam coal is burned under a good boiler for the electric lights, and that the gas is obtained from a bituminous coal.

Digitized by Google

A NEW UNDERGROUND CONDUIT.

The Hurlbut Flexible Conduit Co. exhibit specimens of their conduit at 157 Broadway, New York. It would seem to merit examination and attention on the part of all interested in underground work. It is made of vitrified fire clay, the joints constitute an essential feature, being made sufficiently flexible to meet any ordinary strains, and remaining, it is claimed, water and gas tight.

ELECTRIC LIGHT LITIGATION.

At Trenton, N. J., on December 23, the Edison Electric Light Co. began 11 suits against Westinghouse, Church, Kerr & Co. representing the Westinghouse Electric company, of Pittsburg, for injunctions and damages for the infringement of electric light patents.

ELECTRIC LIGHTING AT CANNOCK CHASE COLLIERIES.

During the meeting of the British Association a paper was read on this subject by A. Sopwith, which has some points of interest. The author pointed out the convenience and economy in utilizing the ventilating fan engines for working dynamos, on account of the regularity of speed—which apart from the requirements of an installation is kept within a limit of 1 to 3 per cent., such variation being a gradual diminution or increase—and the fact that such engines run continuously night and day. The fan itself acts to some extent as a regulator, as the tendency to run away on switching out of lights is modified by the increasing resistance of the air. The addition of counter-shafting in cases of slow running fans, or single pulleys in case of quick running fans, is an easy and inexpensive matter.

Allusion was made to the small extra consumption of coal in practice, and the merely nominal value of the slack which is consumed. In further connection with the working expenses, viz., replacement of lamps, it was mentioned that the underground workings in vicinity of shafts extending to 200 or 300 yards—admit of lamps being worked considerably below power with sufficient effectiveness, and actual lives were given—including breakages—showing at one pit an average of 2270 hours. The men who are required to act as examiners of machinery, and have no specifically regular work to do otherwise, replace lamps and attend to any occasional work connected with installation. As a matter of fact the three installations now working at Cannock Chase have not necessitated the employment of an extra man.

The only original feature—at least the author presumed it to be so—is the utilization of old iron and steel pit ropes for main and branch conductors. From four to five miles of ropes are worn out annually, varying from $\frac{5}{8}$in. to $1\frac{1}{2}$in. diameter and over. In the case of shafts, in order to avoid the injurious effects of water, the ropes are encased in wood boxes strung down the side of shaft, and roughly insulated on brackets. Underground, one of the ropes is simply wrapped with old battice cloth or tarpaulin. On the surface the ropes are laid in brick channels filled in with gas tar and coal dust, but it appears from the last trials that it is sufficient to lay the ropes side by side in the same material; there is no appreciable loss of current.—*Engineer and Trades Advertiser* (Glasgow).

NEW SUBWAY MANAGEMENT.

At the annual meeting of the New York Subway Construction Co., held recently, new directors and officers were elected. Edward Lauterbach was chosen president, William H. Woolverton, president of the New York Transfer Co., vice-president; A. S. Dodd, treasurer of the Metropolitan Telephone Co., treasurer, and William J. Sefton, secretary. The board of directors will be composed of the president and vice-president; E. E. Gedney, cashier of the North River Bank; Theodore N. Vail, president of the Metropolitan Telephone Co.; Robert M. Galloway, vice-president of the Manhattan Elevated Railroad; Edward J. Hall, Jr., general manager of the American Telegraph and Telephone Co.; Richard A. Elmer, president of the American Surety Co.; Frederick Lovejoy, president of the Ball Electric Light Co., and Samuel Carpenter, general passenger agent of the Pennsylvania road and president of the Iron Steamboat Co.

Mr. Lauterbach in his report rehearsed the history and present condition of the company, and suggestions were made looking toward ample preparations for extensive work in the spring. This work will be done by a sub-construction company, to be known as the Phœnix Construction Co. Mr. Lauterbach said that the names of its directors would not be given to the public just yet, as the organization was not yet complete. It is expected that its composition will show the pro-rata interest of the leading telegraph, telephone and electric light companies in the new method of work. It has already secured the contract for 800 miles of duct, and it will deposit a bond with the Construction company as security for the faithful performance of the contract, which in turn will protect the bond of the Subway Construction Co. with the commission. A board of engineers, composed of representatives of the companies, will select the materials for approval.—*Electrical World.*

THE TELEPHONE.

The following statistics are from a recent pamphlet received by the secretary of the National Telephone Association, from M. Berthon, of Paris.

Countries.	Exchanges.	Subscribers.	Largest Exchange.	No. of sub'rs in largest exchange.
Germany	91	14,733	Berlin	4,248
Austria	11	3,032	Vienna	946
Belgium	7	3,365	Antwerp	1,020
Denmark	2	1,370	Copenhagen	1,336
Spain	3	594	Barcelona	300
France	20	7,175	Paris	4,054
Great Britain	89	15,114	London	4,193
Italy	16	8,346	Rome	2,054
Holland	8	2,493	Amsterdam	1,195
Portugal	2	350		
Russia	20	5,280	St. Petersburg	1,100
Sweden	15	5,705	Stockholm	3,825
Switzerland	36	4,900	Geneva	1,068
Total	320	72,457		

The government bill in the suit against the American Bell company in Massachusetts was filed at Boston, on January 13. The defendants have till the first Monday in March, to file an answer, and the beginning of the trial may be reached five or six weeks later. The bill is practically the same as that filed at Columbus. The chief point of novelty is alleged invalidity because Bell did not file a model, in compliance with patent office rules.

The Supreme Court at Washington, has begun the hearing of argument in the appealed telephone cases. It is expected that all questions involved in the various attacks that have been made upon the Bell patent will be finally determined by the court in passing upon the appeals. Seven justices sit in the case, Justice Woods being absent, and Justice Gray declining to sit on account of the interests of some of his relations in the stock of the American Bell Telephone Co.

English and American Telephone Charges.

According to a recent statement, says the *Electrical Review*, London, the charges for telephonic service in this country compare very favorably with those which prevail on the other side of the Atlantic. In New York, the annual exchange rate is £31 5s.; in Chicago, £26; in Philadelphia and Boston, £25; and in Baltimore and St. Louis, £21. In the United Kingdom the rates are as follows: London, Liverpool, Glasgow and Manchester, £20; Edinburgh, £15; Bristol, 15; Sunderland, £14; Dublin and Newcastle, £12; Plymouth, Bournemouth and Portsmouth, only £10 per annum.

Belgium—Long-distance telephony is coming more and more into use. By ministerial decree the systems of Brussels, Louviere, Charleroi, and Mons have been joined, and communication was to be opened late in December. Negotiations are pending between Belgium and Germany for the establishment of a telephone service between these countries. Direct communication between Berlin and Brussels will not be attempted; but a line will be established between Brussels and Verviers, which might possibly be extended to Cologne.

SUBMARINE CABLES.

The Commercial Cable Co. continues to hold its own in the transatlantic competition. The excellence of its service as well as its pluck and its liberal business policy commend it to the esteem of the business world. The munificence of Mr. Mackay has again rewarded handsomely the faithfulness of the staff, the employés in this country and Europe having received a Christmas gift of a half month's salary.

Lieut. I. H. Weber, of the United States Signal Corps, has successfully repaired the cable across Vineyard Sound, cut by the steamship "Wilkesbarre" some time since. The work of securing the cable and splicing it in two places proved a very difficult undertaking, requiring eight days of constant labor. The expense to the government for this work will reach the sum of $600. A sign, with letters of unusual size, has been placed at both landing places, and can be plainly seen for a long distance out in the Sound.

ELECTRIC LIGHT AND POWER.

The experts who have been examining the feasibility of electric motors for the Third avenue surface road have reported that such a motive power is entirely practicable. The only question now seems to be one of expense. It will be a fortunate thing for New York if the company finds an efficient electrical system that will be cheap enough for its purpose. In that event we may hope to see the city rid at no very distant day of horses as a motive power on street car lines. To get rid of the many thousands of horses so employed would add to the cleanliness and health of the city, and be a great gain in the way of saving unnecessary suffering to animals.

Digitized by Google

The Charlestown (Mass.) Gas and Electric Light Co. have a very efficient power plant. The steam plant as constructed consists of a six-foot tubular boiler set with a Jarvis patent setting, and an Armington & Sims engine, and connected direct with the dynamos by belting, no shafting being used. By the use of the National Feed Water Heater the temperature of the water is raised 210 degrees F. and there maintained. At the Charlestown lighting station the fuel used is what is called breeze or coke screenings. This fuel is thoroughly wet before firing, taking about 40 per cent. of moisture. In the process of burning, the moisture in the coke is converted into hydrogen gas; the boiler furnace is so arranged that hot air is delivered on top of the fire; this uniting with the hydrogen gas from the moist coke makes a hydro-oxygen or compound blowpipe flame, the hottest flame known to science, and the result is the boiler furnace is filled with a volume of gas flame, using fuel that is supposed to have all the gas taken out of it in the retorts. When this class of fuel is sold, it generally brings about $1 a ton. Taking it on this basis it costs the Charlestown Gas Co. about $1.50 a night for fuel to run all night 40 full arc lamps.

The Lynn (Mass.) Electric Lighting Co. have in use one 100 h. p. and four 60 h. p. Westinghouse engines; seven 30 light, one 45 light Thomson-Houston arc dynamos and one 200 light incandescent dynamo of the same make. All were running to full capacity in December, with a demand for more lamps.

The following is the list of prices with which the Boston Electric Light Co.—formerly the Brush and Merchants' companies—begins the new year:

ARC LIGHTS.

1	Arc lamp,	Contract for	12	Months.....	75	cents	per day.

INCANDESCENT LIGHTING.

For 125 c. p. lamps, in series of three.

Contract for	12	months.....	each	50	cents	per day.
"	6	"	"	55	"	"
"	3	"	"	60	"	"

For 60 c. p. lamps, in series of three.

Contract for	12	months.....	each	30	cents	per day.
"	6	"	"	35	"	"
"	3	"	"	40	"	"

For 16 c. p. lamps, in series of eight or its multiple, special rates will be made.

The Edison Electric Illuminating Co., Lawrence, Mass., runs a plant of a capacity of 5,400 10 c. p. lamps—including 1,000 municipal lamps. Their power plant includes two 120 h. p., two 80 h. p., and one 35 h. p. engines. 65 miles of wire are used in the street circuits. The underground system embraces over six miles of tubes, aggregating 18 miles of single conductor. Current is also supplied for 28 electric motors, ranging from one-half to 6 h. p., and running printing presses, elevators, lathes, &c., in various parts of the city. There are the following isolated lighting plants in Lawrence—Pemberton mills, 650 lamps; Arlington mills, 425 lamps; Russell paper mills, 200 lamps; Naumkeag mills, 550 lamps; Upton's Glue Works, 150 lamps.

Manchester, Iowa, will be lighted by electricity. For further information address E. F. Kiem, Dubuque, Iowa.

Webster City, Iowa, will be lighted by electricity. W. C. Wilson, and others, are interested.

Fort Edward is to be lighted by electricity. For further information address Charles H. Hooper.

Lakewood, N. J. will be lighted by electricity. Address C. H. Kimball.

The Badger Electric Light Co., Racine, Wis., is making extensive improvements to its plant.

The Electric Light Co., Belvidere, N. J., will erect new plants at Washington and Hackettstown.

S. Pickering, Cedar, Ky., will establish an electric plant in Tampa, Fla.

East Weymouth, Mass., will be lighted by electricity. Address C. R. Greely or Wm. T. Rice.

The Hempstead Gas Light Co., has received the contract to illuminate the village of Hempstead, N. Y., with electricity.

A stock company is being formed at Winchester, Va., to erect an electric light plant. Address E. Y. Henkle, box 176 Winchester avenue.

The success of the Van Depoele road at Scranton, has been so great that two new companies have been chartered to construct and operate separate lines in that city, and it is said that yet another is contemplated. The present road is 2¼ miles long. Although started about December 1st, since when the track has been, much of the time, in the worst possible condition, its success has been so great, that more cars are ordered. It is said that there is some prospect of the removal to Scranton of the works of the Van Depoele company.

New Incorporations.

The Watervliet Electric Light Co., Watervliet, N. Y. Capital stock, $50,000. Thomas Knowlson, and others, incorporators.

The New York Safety Light, Heat and Power Co., New York city, N. Y. Capital stock, $250,000. Caleb H. Jackson, Pittsburg, and others, incorporators.

The Ashville Electric Light Co., Ashville, N. C. Capital stock, $15,000. J. G. Martin, and others, incorporators.

The Whitewater Electric Light Co., Whitewater, Wis. Capital stock, $25,000. O. P. Posey, and others, incorporators.

The Edison Electric Illuminating Co., Birmingham, Ala. Capital stock, $75,000.

The Plattsburgh Electric Co., Plattsburgh, N.Y. Capital stock, $12,000. George D. Dunham, and others, incorporators.

The Traders Electric Light Co., Biddeford, Me. Capital stock, $20,000. President, O. F. Page.

The Boston Electric Light Co., Portland, Me. Capital stock, $1,000,000. President, Fred. A. Gilbert, New Haven, Conn.

The Norwalk Light and Power Co., Norwalk, Ohio. Capital stock, $25,000. C. H. Gallup, and others, incorporators.

The Litchfield, Ill., Electric Light and Power Co., H. H. Beach, Robt. McWilliams, and others, incorporators.

The Franklin Electric Light Co., Montague, Mass. Capital stock, $5,000. W. D. Russell, and others, incorporators.

The Naugatuck Electric Light Co., Naugatuck, Conn. Capital stock, $15,000. E. H. Carrington, and others, incorporators.

The Litchfield Electric Light and Power Co., Litchfield, Ill. Capital stock, $15,000. Henry H. Beach, and others, incorporators.

The Plymouth Light, Heat and Power Co., Plymouth, Mass. Capital stock $15,050. Treasurer, George W. Shonk.

The Hillsdale Electric Light Co., Hillsdale, Mich. Capital stock, $15,000. Henry A. Branch, and others, incorporators.

The Wagner-Fisher and Electric Light and Power Co., Jefferson City, Mo. Capital stock, $18,000. W. W. Wagner, and others, incorporators.

The Greenfield Electric Light and Power Co., Greenfield, Mass. Capital stock, $10,000. John H. Sanderson, and others, incorporators.

The Standard Electric Light Co., Chicago, Ill. Capital stock, $300,000. Lucius J. M. Malmin, and others, incorporators.

Meriden Electric Light Co., Meriden, Conn. Capital stock, $35,000. A. Chamberlain, and others, incorporators.

The Fort Dodge Electric Light Co., Fort Dodge, Iowa. Capital stock, $25,000. President, L. Blanden.

The Edison Electric Light Co., Philadelphia, Pa. Capital stock, $1,000,000. Treasurer, Philip F. Kelly, 3d and Chestnut streets.

The Lyons Electric Light and Power Co., Lyons, Kas. Capital stock, $30,000. President, Seth Warren, Biddeford, Me.

The Saco and Biddeford Electric Light Co., Saco, Me. Capital stock, $10,000. President, Seth Warren, Biddeford, Me.

The Buffalo Electric Light and Power Co., Buffalo, N. Y. Capital stock, $10,000. Chas. G. Curtis, and others, incorporators.

Foreign.

Hawaii—The royal palace is now lighted by electricity, and Honolulu is soon to have an electric light plant.

Hungary.—Buda-Pesth seems likely to have an electrical railway soon. The project has been on foot some months. A concession is expected shortly from the city council. The contractors for the work will probably be Messrs. Lindheim & Co. of Vienna; Siemens & Halske, of Berlin; and Moriz Balázs, of Buda-Pesth.

Austria—In a paper read before the Vienna Society of Electricians, Mr. F. Ross gave some figures showing the actual working cost of the electric light in certain theatres, where it has been in use for a sufficiently long period for a definite estimate to be formed. The prices quoted exhibited extreme variations; for instance, at Carlsbad, where the motive power is obtained from a gas engine, 1,000 ampere hours at 100 volts, costs $13,00, while at Brunn, with steam power, the cost is only $4,35. At Prague, also with steam power, the cost is $6.25.

Brazil—It is stated that the Julien system of electric traction will shortly be introduced on the Rio de Janeiro tramways. The first trials will take place at the commencement of the year.

Digitized by Google

MANUFACTURING AND TRADE NOTES.

There is more demand for electric lights from abroad just now than ever before. The American Electric Manufacturing Co. has made a happy combination. It has arranged with the well-known electrical firm of Wockatz & Co., of Gothenburg, Sweden. The firm is to become the wholesale agents of the American Electric Manufacturing Co. for Norway and Sweden. They have done a very large business for the Edison company, and they expect to sell very large amounts of arc light apparatus. The arc electric light plants have not been so extensively handled abroad as the incandescent; but this new deal of the American company will doubtless give an impetus to arc lighting in the old world.

The Lane & Bodley Co., of Cincinnati, have been awarded the contract for a pair of 24 x 60 Corliss engines, four boilers, cable driving and tension machinery, a complete plant for two cables for the Mt. Auburn Cable railroad of that city.

Messrs. Seth W. Fuller & Holtzer, of Boston, have recently added to their list of electrical apparatus an electric wind indicator, for residences, hotels and public buildings. The indicator, having a compass dial and pointer, is connected by an electric cable with a weather vane on the roof. It may thus be placed in any desired room of a house or public building. It may be worked on either closed or open circuit. In the former case the indication of the direction of the wind is continuous, the pointer following constantly the motion of the wind vane. When the open circuit plan is used an indication may be obtained whenever desired, by pressing a contact knob at the indicator.

The Edison Machine Works have established a department for the manufacture and supply of shafting, pulleys, hangers, couplings, &c., for general purposes. Their facilities for the manufacture of heavy and light machinery are such that they should be able to compete successfully with the best and cheapest in the line mentioned above. They have established a salesroom at 121 Chambers street, N. Y.

The Splitdorf Insulated Wire Co., Brooklyn, capital stock $10,000, has been incorporated. Henry Splitdorf, New York city, and others, incorporators.

The Clark Electric Co., Owego, N. Y., has been incorporated. Capital stock, $3,000,000. James H. Seymour and others, incorporators.

The Farmer Electric Manufacturing Co., Portland, Me., has been incorporated. Capital stock, $1,000.000. President, Moses G. Farmer, Eliot, Me.

The Chrome Steel Works, of Brooklyn, N. Y., desire the address of every reader of this paper who has in use a stamp mill or rock crusher, for the purpose of making them a guarantee proposition which will enable the user to make a trial and test of their chrome steel shoes, dies and crusher plates.

From *El nacional*, of Lima, Monday, Nov. 15th, 1886. "It is proven that the Yankees show wit in the recommending of their inventions and of the goods they offer for sale. We have before us a pamphlet of *Mr.* Chrome Steel Works, who offers the best steel for all kinds of work, and as a proof he asserts that he and a friend of his have escaped four times from the penitentiaries of as many different cities in that country, thanks to his profound acquirements and to the steel he employed to cut the safety-bars of the prisons mentioned. In order to prove finally that he has no rival, he states that he is at present in the penitentiary in Brooklyn, and that his escape is impossible because the doors and safety bars of the cells are of steel made by himself."

Messrs. Walter T. Glover & Co., London, electrical wire and cable manufacturers, announce that Mr. Henry Edmunds, of 2 Victoria Mansions, Westminster, has now become a partner in their firm, and will have the conduct of their London business at 10 Hatton Garden, E. C. Mr. Edmunds' name is well known in connection with the introduction into Great Britain of the Farmer-Wallace, Brush, and Hochhausen systems of electric lighting; and, into the United States, of the Swan incandescent lamp, and the Vitrite Co.'s. patents.

The firm of Vallee & Bro., 1210 Market street, Philadelphia, manufacturers of and dealers in electrical supplies, and contractors for electric and pneumatic work, has been dissolved, and the business reorganized under the style of Vallee Bros. & Co. A change of location has been made to 932 Arch street.

PERSONAL MENTION.

On Christmas Eve the employés of the Government Telegraph Service at Battleford, Saskatchewan Ter., called upon Mr. Hartley Gisborne, district superintendent, and for themselves and absent associates presented him with an address and a rich silver tobacco box, as a small token of their personal esteem, and recognition of his ability as a superintendent.

Mr. Thomas A. Edison has been ill with a slight attack of pneumonia at his house in Llewellyn Park, Orange, N. J., but, happily, is now reported to be beyond all danger.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER, *by* Pope & Edgecomb, *Solicitors of Patents for Electrical Inventions, 11 Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From December 21, 1886, to January 11, 1887 (inclusive).

Alarms and Signals:—*Non-Interfering Street Box for Fire Alarm Telegraph Systems*, A. Anderson, 354,761. *Annunciator and Alarm Signal*, J. W. Frost, 354,856. *Electric Fire Alarm or Thermostat*, C. E. Kells, Jr., reissue, 10,791, December 21. *Electric Value-Controller, and Thermostat Combined*, F. A. Price, 354,932, December 28. *Electrical Indicator*, W. H. Chapman and B. C. Donahue, 355,382. *Electric Alarm*, C. E. Chinnock, 355,384. *Signal Box*, A. Meyer, 355,548, January 4. *Electric Annunciator*, P. Seiler, 355,791. *Safe-Guard Against Boiler Explosions*, J. E. Siebel, 355,793. *Electric Push Button*, F. R. Brainerd, 355,858, January 11.

Clocks:—*Electric Clock-Winding Attachment*, J. Broich and A. E. G. Luebke, 355,434, January 4. *Circuit-Breaker for Primary Electric Clocks*, V. Himmer, 355,820. *Primary Electric Clock*, same, 356,069, January 11.

Conductors, Insulators, Supports and Systems:—*Underground Conduit*, J. S. Du Bois, 354,892. *Underground Electrical Conductor*, F. B. Crocker, 355,063. *Wire and Pipe Supporting and Snow Removing Apparatus*, S. D. Locke, 355,185, December 28. *Underground Wire and Steam Street Conduit*, same, 355,330. *Terminal for Electric Conductors*, F. C. Watkins, 355,423. *Cable Hanger*, G. L. Wiley, 355,491, 355,492 and 355,493, January 4. *Conduit for Electric Wires*, G. D. Sutton, 355,798. *Machine for Covering Conductors with Lead*, E. C. Sloan, 355,843. *Apparatus for Incasing Wires with Lead*, same, 355,844. *Electrical Subway*, R. A. Denison, 355,867, January 11. *Pin-Holder for Electric Wire Insulators*, M. Hanks, 355,165, December 28.

Dynamos and Motors:—*Dynamo-Electric Machine*, E. A. Sperry, 354,945 and 354,946, December 28. *Dynamo-Electric Machine or Motor*, C. G. Curtis and F. B. Crocker, 354,538. *Dynamo-Electric Machine and Electric Motor*, C. G. Curtis and S. S. Wheeler, 354,539; S. S. Wheeler and C. G. Curtis, 354,588, December 21. *Electric Motor*, H. M. Paine, 355,024, December 28; J. H. Linville, 355,771, January 11. *Electric Motor for Railways*, W. H. Knight, 354,793. *Regulator for Dynamo-Electric Machines*, J. H. Irwin, 354,791, December 21. *Regulator for Electro-Magnetic Motors*, W. L. Stevens, 355,729. *Current Collecting Device for Dynamo-Electric Machines*, D. Williamson, 355,738, January 11.

Galvanic Batteries:—*Electrolyte and Depolarizer for Galvanic Batteries*, W. C. Quimby, 355,412, January 4.

Ignition:—*Electric Igniter for Gas Engines*, F. Bain, 354,881, December 28.

Lamps and Appurtenances:—*Electric Lamp*, H. R. Boissier, 354,530; C. D. Jenney, 354,639, December 21. *Electric Arc Lamp*, R. F. Jones, 355,172, J. Brady, 355,120, December 28. *Incandescent Lamp*, A. S. Hickley, 354,788, December 21, W. L. Voelker, 356,019, January 11. *Electric Lighting*, J. E. H. Gordon, 354,781. *System of Electric Lighting*, same, 354,783. *Means for Lighting Railway and other Signal Lanterns by Electricity*, same, 354,782. *Cut-Out for Electric Arc Lamps*, W. C. Walter, 354,847, December 21. *Mast-Arm for Electric Lamps*, T. B. Keeler, 355,400. *Method of Suspending Electric Lights*, H. F. Edwards, 355,443. *Safety Circuit for Electric Lights*, E. T. Greenfield, 355,446, January 4. *Process of Manufacturing Carbons for Electrical Purposes*, W. L. Voelker, 356,020. *Method of Drying Incandescent Electric Lamp Bulbs*, A. L. Reinmann, 355,714, January 11.

Measurement:—*Electric Meter*, J. E. H. Gordon, 355,871, January 11.

Miscellaneous:—*Electrical Distributor*, R. H Mather, 354,606. *Electro-Magnetic Boiler Cleaner*, G. W. Hart, 354,637. *Sewerage System*, J. H. Clark, 354,688. *Electrical Pumping Apparatus*, M. A. and A. Michales, 354,838. *Electric Circuit Closer*, J. Geary, 354,858, December 21. *Circuit Closer*, W. B. Manny, 354,919. *Process of Extracting Nickel and Cobalt from Ores*, D. Mindeleff, 354,923. *Electro-Therapeutic Appliance*, J. Charles, 355,059. *Electric Heat Regulator*, R. L. Guion, 355,164, December 28. *Coupling for Electric Conducting Wires*, G. A. Carpenter, 355,380. *Prevention of Induction in Electric Circuits*, J. O. Stockwell, 355,420. *Coupling for Electric Wires*, H. Howson, 355,611, January 4. *Electro-Magnetic Cut-Out*, F. H. Wilmarth, 355,739. *Means for Preventing Noise Occasioned by Vibrations of Telegraph Wires*, P. E. Bardonnaut, 355,753. *Magnetic Water-Level Indicator*, J. J. Ghegan, 355,815. *Electro-Magnetic Regulator for Valves*, G. M. Sternberg, 355,892. *Electro-Magnetic Regulator for Dampers and Valves*, same, 355,893 and 355,894. *Electro-Magnetic Regulator for Valves and Dampers*, G. M. Sternberg and A. A. Lehman, 355,895. *Electric Cut-Out*, A. E. Paige, 356,008. *Controlling Valves by Electricity*, F. Bain, 356,024. *Electric Current Indicator*, J. W. Howell, 356,041 and 356,042, January 11.

Railways and Appliances:—*Railroad Signal*, G. D. Burton, 354,827, December 21; S. T. Street, 354,992. *Signaling Apparatus for Railway Trains*, J. H. Bickford, 355,055, December 28. *Railway Telegraphy*, L. J. Phelps, 355,468, 355,469, and 355,470, January 4.

Telegraphs:—*Telegraph Instrument*, J. Steiner, 354,814 and 354,815, December 21. *Telegraphic Switch*, J. Absterdam, 354,996, December 28. *Telegraph Receiving Instrument*, W. Arthur, 355,431. *Printing Telegraph*, D. E. Pike, 355,662, January 4. *Telegraphy*, R. G. Brown, 355,860, January 11.

Telephones, Systems and Apparatus:—*Telephone*, C. E. Egan, 355,685 and 355,687. *Magneto-Telephone*, H. E. Waite, 355,734, January 11. *Telephone Transmitter*, D. Drawbaugh, 354,541 and 354,542; W. L. Voelker, 354,818, December 21; F. C. Watkins, 355,426, January 4; C. E. Egan, 355,686; H. P. Pratt and L. O. McPherson, 355,838; J. C. H. Stut, 355,952; J. P. Freeman, 356,034, January 11. *Telephone Receiver*, H. A. Schneekloth, 355,032; A. E. Dolbear, 355,149, December 28; F. C. Watkins, 355,424; January 4. *Telephonic Apparatus*, J. F. McLaughlin, 355,189. *Telephone Appliance*, same, 355,190. *Telephone Check Apparatus*, D. J. Smith and D. Sinclair, 355,226. *Mechanical Telephone Exchange*, G. F. Shaver, 354,942, December 28. *Mechanical Telephone*, T. H. Weinhaus, 355,363, *Telephone Signal*, C. E. Chinnock, 355,383. *Central Office Telephone Switch-Board*, F. C. Watkins, 355,425, January 4. *Telephone Cabinet*, C. Wittenberg, 355,741. *Alarm and Register Attachment for Telephones*, same, 355,742. *Telephone Register*, same, 355,743. *Telephone-Toll Collector and Register*, same 355,744 and 355,746. *Register Attachment for Telephones*, same, 355,745. *Telephone Switch System*, C. C. Gould and W. Smith, 355,928, and 355,929. *Grounding Switch for Telephone Instruments*, C. C. Gould, 356,038. *Telephone Switch*, C. A. Hitchcock and W. Burnley, 356,040, January 11.

THE ELECTRICIAN
AND
ELECTRICAL ENGINEER.

Conducted by F. L. POPE. G. M. PHELPS, JR., R. W. POPE, } Associate Editors.

PUBLISHED MONTHLY BY

THE ELECTRICAL PUBLISHING CO.,

115 Nassau Street, New York city.

European Agent, F. H. WEBB, 4, The Sanctuary, Westminster London, S.W., Eng.

TERMS OF SUBSCRIPTION.

United States and Canada,	per annum,	$3.00
Four or more Copies, in Clubs (each)	"	2.50
One Copy, Four Months,		1.00
Great Britain and other Foreign Countries within the Postal Union	"	4.00
Single Copies,		.25

[*Entered at the Post Office at New York, N. Y., as second class mail matter.*]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

NEW YORK, MARCH, 1887.

ANNOUNCEMENT TO SUBSCRIBERS.

WE are pleased to recognize the fact that a principal source of the growth of our subscription list is the favorable commendation of the ELECTRICIAN AND ELECTRICAL ENGINEER by those who are already subscribers, to their friends and acquaintances

We shall continue our endeavors to deserve your appreciation and good-will, by keeping up, and if possible improving the quality of our paper. To any of our present readers who may find it in their way to increase our list, we offer rates for 1887 as follows:

For your own subscription	and	1	new name	.....		$5 00
"	"	"	" 2	"	.....	7 00
"	"	"	" 3	"	.....	9 00
"	"	"	" 4	"	.....	10 00

This offer will hold good until April 1st.

The *Telegraphic Journal and Electrical Review*, London, will be supplied for one year in conjunction with the ELECTRICIAN AND ELECTRICAL ENGINEER for the additional sum of $4.00 with any subscription.

In addition to the usual methods prescribed for making remittances, money orders issued by the American, United States or Wells Fargo express companies will be found safe, cheap, and convenient.

Very respectfully yours,

ELECTRICAL PUBLISHING CO.,
115 Nassau St., New York.

SPECIAL ANNOUNCEMENT.

BY arrangement with the *Electrical World*, New York, we are able to make the attractive offer of that valuable and enterprising weekly journal in conjunction with the ELECTRICIAN AND ELECTRICAL ENGINEER for one year for $5.00 to new subscribers. To our present subscribers we will supply the *Electrical World* one year for $2.50.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

IF anything were needed to establish beyond doubt the usefulness of the National Electric Light Association and its periodical gatherings of technical and commercial workers in the field of electric illumination, it was afforded in the significance and scope of the work done at the Philadelphia meeting two weeks ago. Five meetings have now been held, each showing a gain in membership, and, still more important, an advance in the class of work undertaken, and in the manner of its execution. The association is doing much in furtherance of a rational and intelligent development of an industry that, like some boys, has reached adult proportions almost at a bound, and like the vigorous stripling, needs a good deal of shaping and discipline.

The tone of the convention throughout was frank, manly and earnest; frank and manly in general acknowledgement of the shortcomings of much of the work done in earlier stages of electric lighting, and of the room for improvement in present methods; and earnest in seeking and discussing means of improvement. Much as there is for congratulation in the present state of electric lighting as an art and industry, the association spent no time in felicitations, but promptly settled down to its work.

A full report of the proceedings is given in our present issue.

Among the important subjects acted upon by the convention, after the reading of able papers relating to them and discussion by the members, were the adoption of a standard wire gauge, the proper insulation of wires and apparatus, and patent office reforms. The first of these is a topic that has haunted the meetings of the association for a long time, everybody recognizing its importance. It was once acted upon, the convention adopting the new British gauge. This action of the association seems to have had no appreciable effect upon the practice of its members, the rather amusing result being brought out at the Philadelphia meeting that but one purchaser of wire had ordered by the adopted gauge. The gauge system proposed and tentatively adopted at Philadelphia is to be commended for its simplicity. It seems to cover all ordinary needs of electricians, and to offer a more readily comprehensible series of numbers than any existing gauge. Its introduction, if accomplished, will be a step towards a more general use of the metric system of measurement in this country.

The subject of insulation, treated at length in one able paper and touched upon largely in another, received well-merited attention at the hands of the convention. A thoroughly competent committee was appointed to investigate the subject and report at the August meeting. In our judgment no feature in the installation of electric light plants is so urgently in need of reform as that of

Digitized by Google

wiring. Mr. I. N. Miller called attention through the columns of the ELECTRICIAN AND ELECTRICAL ENGINEER, October, 1886, to the short-sighted policy of continuing the use of the so-called "underwriters wire" for out-door construction. Its defects and dangers, in many situations, have been clearly shown. The report of the insulation committee at the August meeting, followed by proper action by the association, may be expected to effect much needed reform in wiring, both in-doors and out.

Patent office reform is a topic of such wide interest, touching the welfare of so many people, that the action of the Electric Light Association in seeking needed legislation at the hands of Congress, should have hearty and wide-spread support.

Electric transmission of power received a large share of attention from the convention. The papers read upon this topic, and the ensuing discussions, were very significant of the general confidence in the early establishment of profitable business in the manufacture and introduction of electric motors.

The recent convention is generally regarded as the most successful yet held, and its work can hardly fail to redound to the best interests of all who are in any way connected with electric lighting, whether members of the association or not. The association is to be congratulated upon the re-election of President Morrison for another term. His common sense and energetic methods as a presiding officer contribute largely to the orderly and expeditious despatch of business. The August meeting will be looked forward to with much interest, not only for the results of action taken on important topics at Philadelphia, but for the pleasure found in the meeting of so large a number of earnest workers in a common field.

THE EDISON INCANDESCENT LAMP CASE IN ENGLAND.

ON the 31st of January the Court of Appeal gave judgment in the case of the Edison & Swan Electric Light Company *vs.* Woodhouse & Rawson, sustaining the decision given last summer by Mr. Justice Butt for the Edison & Swan Company. The appeal was heard by Lords Justices Cotton, Fry and Bowen. The three judges were divided in their opinion, Lord Justice Cotton dissenting from the judgment for plaintiff.

Those of our readers who have followed the litigation[1] will remember that in the original action the contention turned chiefly upon the construction of the following claim of one of Mr. Edison's patents: "The combination of a carbon filament within a receiver made entirely of glass, through which the leading wires pass, and from which receiver the air is exhausted for the purposes set forth." Inasmuch as the combination of an exhausted glass receiver, leading wires passing through it, and a fine carbon rod as an incandescent conductor, had been shown in lamps made and exhibited by Swan before the date of the Edison patent, the meaning of the word "filament" became the pivotal point of the case. In the original trial by Mr. Justice Butt the court held that a carbon filament was characterized by the qualities of flexibility, resiliency, and a high electrical resistance. On the appeal it was held by Lords Fry and Bowen that Mr. Edison's lamp differed from Swan's in a crucial point, "that the departure, though slight, had all the merits of a new invention. Mr. Edison used the filament instead of the rod for a definite purpose, and by the diminution of the sectional area made a physical law subserve the end he had in view. The smallness of size, therefore, was no casual matter, but was intended to bring about, and did bring about, a result which the rod could never produce, and so converted failure into success."

In expressing his dissent from the conclusions of his associates Lord Justice Cotton gave his opinion that an examination of the whole specification of Edison's patent did not justify a claim for a combination including carbon filaments generally. Finding the term "filament" to have had no recognized definition in respect to the subject-matter at the time of the invention, he disagrees with the assignment to it of the qualities of flexibility and resiliency, and holds that the only flexibility the inventor had in mind was flexibility of the original material.

The definition of a "filament" adopted by the majority of the Court of Appeal seems broader than that of the lower court; in fact it scarcely leaves room for any practicable carbon conductor in an incandescent lamp.

A further appeal, to the House of Lords, was indicated by remarks of counsel at the conclusion of the case.

1. See ELECTRICIAN AND ELECTRICAL ENGINEER, Vol. v., pp. 241-243.

WE publish elsewhere a translation (for which we are indebted to the columns of the *N. Y. Evening Post*) of an address by Dr. Werner Siemens, on "Science and the Labor Question," delivered at Berlin before the Congress of German Naturalists. Our readers are so well acquainted with Dr. Siemens' distinguished position as an investigator and inventor, particularly in the field of electricity, that they cannot fail to find interest in the conclusions of so trained a mind as his on a question so vital at this time as the labor problem.

As we surmised in our February number, Judge Van Hoesen's decision against the Subway Commission in their application to enjoin the New York Underground Telegraph Co. has encouraged the promoters of other underground plans to come forward again. The New York Electric Lines Co. has applied to the commission for approval of its plans, alleging that it had demand for over 1,000 miles of underground conductors. Judge Van Hoesen's decision precludes the establishment of a monopoly of underground conductors by the commission, confining their power to the approval of plans, and leaving the question of permits, that is, as to where and when conduits for electrical conductors may be laid, to the city authorities. The Subway Commission is, consequently, seeking further powers from the legislature.

DESIRING to give our readers the entire proceedings of the meeting of the Electric Light Association in one number, we have increased the size of the present issue by eight pages.

THE ECONOMY AND EFFICIENCY OF UNDERGROUND ELECTRICAL CONDUCTORS IN CITIES.

BY DAVID BROOKS.

When Mr. W. H. Preece, the chief electrician of the English post-office department, was in this country two years since, he stated that whenever the government could get as many as 15 electrical conductors into one route or channel, they found it both advantageous and economical to place them underground. Mr. Preece's experience with underground electrical conductors, as compared with overhead conductors, was almost entirely with the underground conductors insulated with gutta-percha.

The cost of a No. 18 British-gauge wire, insulated with gutta-percha, according to the government standard, is about $75.00 per mile. These conductors are drawn into cast-iron pipes, usually buried beneath the sidewalks at an average depth of two feet below the surface. This is the cost of the conductors themselves; but the expense of the trenching, the iron pipes, the drawing-in and splicing, brings the cost of these wires when laid to $100.00 or over per mile. Gutta-percha insulation is expensive.

By the use of oil, and a textile covering for the wire, instead of the gutta-percha insulation, we can lay three times as many of those conductors in this country for the same amount of money. In Europe we can lay at least five times as many conductors of the same gauge for the same expense.

DURABILITY.

The next question for consideration is the comparative durability of the different systems. Gutta-percha, or India rubber, like all vegetable or organic matter, undergoes disintegration and decay, but much depends upon the condition in which it is used. As it is used in England, it lasts from seven to ten years. It is exposed to the influence of damp and impure air. The French use the same kind of insulation, but they draw from five to seven conductors into a lead pipe, which is afterwards pressed tightly around the group of conductors, so as to exclude the air; and by that means they have made the insulation last thirty years; so I was informed in 1881 by the French electrical engineers; and for all I know those conductors are working yet. Within the last few years they have laid a large amount of those lead-covered cables, drawn into cast-iron pipes of larger diameter, and have wires working now underground from Paris to Marseilles and other cities of the Republic. Gutta-percha, when buried in the sea, and away from the influence of the air and the light, is said to be practically imperishable; but when suspended in the Paris sewers, and unprotected by the lead covering, it lasts but a short time.

The life of an insulator is dependent upon its durability. As a gutta-percha insulating material goes into decay, it does not become a conductor of itself, but it cracks and then admits moisture, and the moisture in the cracks becomes a conductor. Conductors insulated with India rubber made from old shoes have every appearance of presenting as high an insulation as those insulated with fresh Para rubber; but the life of the former is comparatively short as an insulator, because the material itself has lost its vitality.

There are different methods of preserving materials of all descriptions, but as a general thing almost any organic matter and the metals can be preserved if we protect them from the effects of light, heat, moisture and the air. As a rule, heat is not a factor in the decay of electrical insulating materials, for, as commonly used, they are not subjected to the influence of abnormally high temperatures.

I insulate underground wires with oil and a textile covering. All traces of moisture, air and light are excluded. There is nothing that can in any way affect the contents of the pipe. The textile covering is preserved by a hydrocarbon, the most stable of all materials, the same that has preserved the linen covering of the Egyptian mummies for thousands of years. The hydro-carbon preserves the inner surface of the pipe, the copper conductors and their covering. No change can take place in the condition of those materials, and, as a consequence, no change can take place in their insulating properties, as the insulation is entirely dependent upon the durability of the insulating materials; or, in other words, the durability is more a question in physics than an electrical question. If I were asked how long a glass insulator would last, I would say just as long as the glass remains whole and entire. I am often asked if the electrical current does not affect the oil. I say, no more than it affects the glass insulator on the poles. Such non-conductors as glass or oil, or any other equally good insulators, are unaffected by a current of electricity.

This much relates to the inner surface of the pipe and its contents. The outer surface of the iron pipe is protected from rust by being enclosed in a wooden box of sufficient dimensions to contain the iron pipe and a concrete covering composed of pitch and sand, which effectually prevents oxidation of the outside surface of the iron pipe. Under these conditions the system can be said to be indestructible except by mechanical means. So much for durability.

THE EASE AND FACILITY WITH WHICH THE SYSTEM IS LAID.

As many as 2,000 feet of trench have been dug, and the lengths of iron pipe screwed together, and the trench filled and repaved in one day. The inside of the pipe having been scoured and polished perfectly smooth, 2,000 feet of cable can easily be drawn in. The oil acts as a lubricator, enabling the cable to slip along easily and without friction. Nor is it necessary that the pipe be laid in a straight line. We go either above or below gas or water pipes, or to one side or the other of any obstruction we meet.

Three three-inch diameter pipes, with carrying capacity of 1,530 conductors, are laid in Calhoun place, Chicago. The wooden box containing these pipes has less than one square foot of section. A mile of cable could be drawn in, in one length, if it were desirable.

By having a short piece of the pipe bent so as to form a ninety-degree segment of a circle, the radius of the circle being two feet, street corners can be turned with ease, and cables have been drawn around two of such corners without producing a sensible or material increase of friction. By the use of the splice-boxes, or hand-holes, as many as 500 splices have been made by one person in a day. In New York, hand-holes were inserted every 45 feet, making it easy to bring out conductors and lead them into adjacent buildings; and they are so introduced, every portion of the wire from the building to the exchange being underground. Of those 800 conductors now in use for two years, not one has failed or cost one penny for maintenance or repairs. Another method is to bring out under the sidewalk, through the cellar to the rear of the building, as many conductors as will be needed in that block. They can be distributed from a short pole easily to any or every building in that block. A property owner would sooner grant this privilege than have poles standing in front of his building, as such poles must necessarily be high, and the snarl of wires radiating from that structure presents a very unsightly appearance.

FOR TELEPHONIC LINES.

The system is peculiarly adapted for telephonic purposes, being free from inductive disturbances and overhearing or eavesdropping. Those having interest in telephonic exchanges should consider the advisability of applying a portion of their earnings to the placing of the conductors underground. They should take into consideration the expense they are now under of having so large a force employed to hunt up and remove "trouble," and the vexatious

Digitized by Google

annoyances occasioned by the frequent interruptions of the overhead service. The outlay incurred in maintaining the force simply to remove "trouble" would pay an interest on a very large amount of capital. They should take into consideration that these overhead conductors are getting weak and brittle from exposure to the atmosphere of cities. The main telephone patent will expire in a little over six years. During this time, with judicious management their conductors can be buried, and the expense of this work paid out of the earnings of the company. A stockholder would part with his stock while it is paying 12 per cent. at a less price than he would were it paying six per cent., if he knew that when the time arrives for the patent to expire the conductors would be underground, and the expense of putting them there paid. Would a competing company easily raise the funds to put down a plant to compete against a company whose plant is already down and paid for? It is evident that the present companies would be as well protected under these circumstances from competition as they are now by the patent itself.

It is also well to bear in mind that since electric lighting came into use many of the telephonic exchanges and telegraph offices have been either destroyed or seriously damaged by fires occasioned by electric light conductors coming in contact with the telephone or telegraph conductors, and this danger will continue so long as these different electric conductors remain overhead. In New York, Brooklyn, Philadelphia, and other places, people have been killed by coming in contact with electric light conductors. Chicago is the only large city that has not suffered in this respect, and the reason is that all the electric light conductors are underground. Chicago is in advance of all other American cities in this underground business. Chicago has one-third more telephone subscribers than Philadelphia. The Bell Telephone Co. of Philadelphia employ 20 more men than the Chicago Telephone Co. to remove interruptions to their circuits. The Philadelphia Co. have no wires underground.

FOR TELEGRAPHIC LINES.

For telegraphic purposes few are aware of the advantages of having the wires placed underground in cities. The glass insulators in cities soon become coated with soot or carbon, and thousands of insulators are in use that will not show an insulating resistance of one megohm. There is as much loss of current over one insulator so situated, in rain and dampness, as there is in twenty miles of the line in the country, where the insulators are clean and affected by moisture only, which is comparatively free from impurities. When lines are worked upon the same set of poles with positive and negative currents, the interference from wire to wire by these currents short-circuiting into each other, commonly called cross-currents, is so great that some of the circuits have to be opened in order to enable the others to be worked. The telegraph officials in Chicago all speak of the great advantage derived in this respect from having their wires placed underground in that city.

FOR ELECTRIC LIGHTING WIRES.

For electric lighting, this system is peculiarly well adapted, both for arc and incandescent. By the use of the splice-boxes and hand-holes the conductors can be brought into the buildings for house-to-house purposes, or into the ordinary street lamp posts. The conductors for such purposes can be drawn in singly or a number of them in a group, as circumstances may require. Oil is the strongest insulation known, or least liable to be affected by currents of high potential and quantity combined.

UNDERGROUND CONDUITS.

Underground conduits first began to be invented in England about the year 1850, and from that time until 1860 many patents were taken out for different forms and materials. But a great many patents have been taken out in this country within the past ten years for that class of inventions. Neither in England nor in this country have the patentees been known as having much or any electrical experience. These various patented conduits are supposed to facilitate repairs by easy drawing in and out. From the nature of the case, conductors placed in these receptacles are continually in need of repairs. The atmosphere of the conduit is full of gases that will soon affect and destroy anything that is put in them. Some of the gases are heavier than the air, and their tendency is to collect and stay in the conduit. They act upon the metals, lead and iron like stagnant water, and no insulating covering of any kind can long withstand the effect. They are always damp, and the inner surface so wet that nothing is gained by having the material of the conduit itself made of a non-conducting substance.

It has been proposed to make these conduits of wood, but such a structure decays very rapidly, as was shown in the early experiments in England. A piece of wood buried in the ground, with the earth packed closely around it on all sides, lasts ten times as long as a wooden box containing damp and impure air. The decay begins on the inner surface of the box, that portion of the box coming in contact with the impure air, and no means have ever been devised to prevent it.

The writer has spent the last four months in Chicago, and has had abundant opportunity to examine the different systems there. That of the Dorsett has fewer conductors and in much shorter lengths than that laid for the Metropolitan Telephone Company, by the writer, in New York, two years ago, which has not cost one cent for repairs nor have any of the wires failed or deteriorated. But in Chicago, although the conductors have been in the ground a shorter length of time than have those I laid in New York, three men are continually employed, in Chicago, in repairing and removing faults or interruptions. The lead covering is often eaten through by rust.

They dare not go near the man-holes with a fire or soldering pot for fear of explosions. I had myself an experience. The Chicago Telephone Company had arranged a man-hole for bringing in the wires, opposite No. 91 Jackson street. When we sent a man into the man-hole with a lantern, to splice the wires, an explosion took place which set fire to the covering of the wires. In order to put out this fire, snow was shoveled on and by that process they got water into the pipe, which delayed our work two days.

A galvanized wire drawn into one of these conduits six months since, when pulled out showed no traces of zinc covering, it having been so affected by the atmosphere of the conduit.

Another objection to these conduits is their cost. I can lay alongside the conduit put down on Sixth avenue, New York, an equal number of conductors that can be got into that conduit, the conductors being of equal insulation and conductivity, for less money than the conduit costs, without wires in it. And I will guarantee the interruptions or failures from every cause to be less in the conductors I lay than those in the conduit, in the proportion of one to one hundred.

LEAD COVERED CABLES.

A lead pipe of sufficient diameter to contain one hundred conductors, costs as much per foot as an iron pipe containing five hundred conductors. If as many as two hundred conductors can be got into one route, it costs no more to place those conductors underground in an iron pipe, than to string them overground in lead pipes, and in the latter position they are liable to injury from fire, as almost every telephone exchange using lead covered cables can testify. If lead covered cables are placed underground they have to be imbedded in asphalt or pitch, to protect the lead covering, and in case of an accident happening to

Digitized by Google

the conductors it is extremely difficult to find and remedy the trouble.

The lead covering is seriously affected, as before stated, by the atmosphere of the conduit, and lead covered cables are extremely unwieldy to draw out of a conduit.

In our system, the cables can be easily drawn out of the iron pipes if occasion demands it. We have only had one such occasion and that was in Chicago, when it became desirable to substitute a 250-wire cable for one which had only 150 conductors in it.

The London *Electrician*, of May, 1886, contains the following experiments with oil as an insulator, by H. C. Frempt :—

"The oil used to insulate the underground wires running into the telephone exchange, at the corner of Broadway and Spring street, New York, is heavier than water. Take two cotton covered wires which have been boiled in that oil, draw them through glass tubes, twist the ends together, and place them in an ordinary glass battery jar. Fill the jar half full of oil, after which water may be carefully poured into the jar and it will remain above the oil. Attaching the poles of a battery to each of these wires, as shown above the glass tubes, no current will be observed as passing from one wire to the other.

"Take a piece of lead pipe containing a cable of cotton covered wires insulated with the same oil in a fluid condition, and cut a hole in the lead an eighth of an inch in diameter. The oil being viscous will ooze out slowly. Place the cable in a jar, and fill the jar with water, the oil will continue to flow till an equilibrium is established, but no current can be passed from one wire to the other or from either wire to the lead pipe. Now, if instead of oil we use in this experiment paraffine, pitch or rosin, the insulation immediately fails.

"Six years since there was a lead covered cable insulated with oil, armored and laid across the Delaware river. The cable contained 50 conductors, not one of which has failed. The cost of this cable of 50 conductors was no more than that of an ordinary gutta-percha insulated cable of five conductors. The gutta-percha insulated cables across the Delaware during this period have been continually subject to mishaps. Many of the conductors have been injured by lightning, although protected by lightning arresters. When the gutta-percha insulation is punctured by atmospheric electricity, it leaves a hole in the insulation in which water enters, by which the current passes to earth. The cable has to be underrun, the leak found and the hole sealed up, but a hole cannot be made in a liquid."

The splice boxes we use will hold two gallons of oil after the splices are covered with oil. When the splices are covered by the oil we can fill the remaining portion of the box with water without affecting the insulation of the conductors.

DYNAMIC ELECTRICITY.

BY CARL HERING.

(Continued from page 64.)

CHAPTER VI.—CALCULATION OF ARMATURES (CONCLUDED).

To illustrate the calculation of an armature by this method, assume that a cylindrical armature is to be designed for supplying the current for 150 lamps at 100 volts.

If the lamps require .65 ampere each, the current in the external circuit will have to be $.65 \times 150 = 97.5$ amperes. If the machine is to be shunt wound the current required for the field magnets may be about 3 per cent. of the total current. The armature having to supply both lamps and field will therefore have to generate 97.5 + 3 per cent. of 97.5 = about 100 amperes. As the machine will not be large, the proportion of energy lost in the armature may be taken as about 5 per cent., which will be about 5 volts. As the leads to the lamps will diminish the potential, the machine must generate a higher electromotive force in order that the lamps may have full 100 volts. For this loss in the leads 5 per cent. may be allowed, thus making the potential at the machine 105 volts, and as 5 per cent. was allowed for the loss in the armature itself, the total electromotive force to be generated in the armature must be about $105 + 5 = 110$ volts. The armature, therefore, must generate 100 amperes at 110 volts.

If the armature is to be well-proportioned and has not too many windings or too few commutator bars, an induction of about 1.2 volts per foot may be generated with well-proportioned field magnets and a velocity of the wire of about 40 feet per second. The 110 volts will therefore require $110 \div 1.2 = 92$ feet of active wire, which must at all times lie between one pole piece and the armature core, that is, must be embraced by one pole piece. As the wire which lies in the neutral part of the field is about 20 to 25 per cent. of the whole amount of wire on the cylindrical surface, the active part is about 80 to 75 per cent. of the whole. Assuming 75 per cent., the whole length of wire on one half of the cylindrical surface will be $92 \div .75 = 123$ feet. As described before, the whole armature wire is, by the nature of the winding, divided into two halves, which are in multiple arc, each half has to generate the full potential of the machine, but carries only half the current. The 123 feet determined as just described from the potential and the volts induced per foot, is therefore the length in one of these halves of the armature wire ; the whole length on the cylindrical surface will have to be twice this, or 246 feet.

The cross section of the wire should be determined from its allowable resistance, in order that the armature shall not absorb more than about 5 per cent. of the whole energy, but as this would be found to complicate the calculations, it is simpler to assume a certain cross section per ampere, and after completing the calculations, find whether this will give about the proper resistance, and if not, the proper cross section can then be readily determined. Assuming 520 square mils per ampere, which, for an armature with few layers will not cause it to heat too much, the cross section of the wire will be $520 \times 50 = 26{,}000$ square mils, as 50 amperes flow through each half of the armature, that is, through each coil or wire. This cross section is very nearly that of No. 5 B. & S. wire, the diameter of which is 182 mils. The insulation will increase the diameter about 15 mils, thus making the diameter of the covered wire 197 mils.

The length and diameter of the armature might be determined as described from its area, which can be calculated from the length and diameter of the wire on its cylindrical surface, but it will generally be found to be simpler to determine the diameter and length by trial, as follows : Assume that there are two layers on the armature, and 56 coils or commutator bars ; these two assumed proportions may afterwards be varied to find whether any others would be better. Try first three turns per coil ; this gives $3 \times 56 = 168$ turns, which, when multiplied by two, gives the total number of lengths or wires lying on the cylindrical surface of the armature, as each turn has two active lengths, one on each side of the armature. This again divided by two, as there are two layers, gives 168, the number of lengths or parallel wires in one layer ; multiplying this by the diameter of the covered wire in inches, namely, .197, gives 33.1 inches as the circumference of the inside layer, which is equivalent to a diameter of about $10\frac{1}{2}$ inches.

As there must be 246 feet of wire on the cylindrical surface, made up of 168 turns of two lengths each, there will be $168 \times 2 = 336$ parallel lengths, thus giving $246 \div 336 = .733$ feet, or 8.8 inches, as the length of the armature core and pole piece. This may be checked by calculating the area of the cylindrical portion of the armature, first,

Digitized by Google

from its diameter and length and then from the diameter of the covered wire, the number of parallel wires and their total length. Both should be the same; the area in this armature is 291 square inches.

As this diameter, 10½ inches, is very large for such a small machine, and quite large as compared to its length, 8.8 inches, it is probable that better proportions could be found. Repeating the calculations for two turns per coil and 56 commutator bars gives the following proportions: Diameter, 7 inches; length of core, 13.2 inches. These proportions appear to be much better, as the length is very nearly twice the diameter.

To find how these proportions will satisfy other conditions it is necessary to assume some speed. This must be based on the mechanical construction of the frame, bearings, and armature. If rigidly supported such an armature may be safely run at 1,200 revolutions. With this speed and a mean circumference of 23.2 inches the inductor velocity will be $23.2 + 12 + 1{,}200 + 60 = 38.8$ feet per second. This is not as high as would be desirable for the best effect and economy, but with such a small diameter a higher velocity cannot be obtained, as it is not advisable to increase the speed. This low inductor velocity indicates that a larger diameter might give better results.

From this inductor velocity and from the assumed induction in volts per foot, determine the required intensity of the field, in order to see that it is not too high. One foot of the wire moves 38.8 feet in one second, and therefore passes through or over an area of $38.8 \times 1 = 38.8$ square feet in one second; in doing so it generates 1.2 volts, as assumed at the outset. From this it follows that it must cut 120,000,000 lines of force in one second, and that these must pass through this area of 38.8 square feet; reducing to inches and dividing gives $120{,}000{,}000 \div (38.8 \times 144) = 21{,}500$ lines of force per square inch, as the required intensity of field, which will induce 1.2 volts per foot at a velocity of 38.8 feet per second. This intensity is not too high and can readily be generated by well-proportioned magnets. If it is found from a similar machine that a greater intensity of field may be obtained economically, the induction in volts per foot may be assumed proportionately higher. For instance, if it is found that 25,000 lines of force per square inch can be generated economically, then the induction may be assumed to be 1.4 volts per foot, as this is in the same proportion to 1.2 as 25,000 is to 21,500, or in other words $25{,}000 + 21{,}500 \times 1.2 = 1.4$. This would decrease the length of the armature in the same proportion, that is, instead of being 13.2 inches, it will be only $1.2 \times 13.2 + 1.4 = 11.3$ inches, showing the importance of having the field as intense as possible.

To find whether the resistance of the armature is too high it is necessary to know what the total length of the wire is, including that around the heads. From actual measurement it has been found that an armature whose length is about twice the diameter of core, the wire on the cylindrical or active surface is about 40 per cent of the whole length. The length of wire on the cylindrical surface has already been found to be 246 feet; as this is 40 per cent. of the whole, dividing it by .40 gives about 615 feet for the total length. As the resistance of No. 5 B. & S. wire is .32 ohms. per 1,000 feet, 615 feet will have .1968 ohms, and as the two halves of the whole length are in multiple arc, the resistance of the armature will be one-quarter of this, or .049 ohms. To see whether this resistance will absorb more than the 5 per cent. allowed for it, find how many watts are absorbed by the armature and divide it by the total amount of energy generated. That lost in the armature is equal to the square of the current multiplied by the resistance, or $100 \times 100 \times .049 = 490$ watts. The total amount of energy generated is 100 amperes $\times$ 110 volts $= 11{,}000$ watts. Dividing the first by the second gives about 4.5 per cent., when the armature is cold, but it will still be within the 5 per cent. when warm.

These calculations show that this armature, whose core is about 7 inches in diameter and 13¼ inches long, will answer all the conditions and will not be out of proportion. But in order to be assured that no other proportions will give better results, they should be varied, and the corresponding changes made, to see how it will alter the final proportions. For instance, fewer commutator bars, as for instance, 48, and say three turns per coil, might give better proportions; there will be $48 \times 3 = 144$ turns, as against 112 in the former case. This would evidently make the diameter larger and shorten the length. A larger diameter enables a greater inductor velocity to be obtained with the same speed of revolution, thus increasing the induction per foot, and thereby decreasing the length of wire. By completing the calculations and making the deductions as described, it can readily be determined which form would probably be the better.

As it is desirable to increase the diameter of the armature in order to get a greater velocity with the same number of revolutions, the following proportions suggest themselves: Assume 64 coils of two turns of No. 5 B. & S. wire. This gives 128 turns, and a diameter of eight inches. With the same strength of field the induction, 1.2 volts per foot, will therefore be increased in the proportion of 7 to 8, giving 1.4 volts per foot. This, for 110 volts, makes the length of the armature 10 inches. The total length of wire (assuming that only 38 per cent. is active on account of the shorter length) is 550 feet, and the resistance of the armature .044 ohms. This is less than before, showing that with these new proportions less wire will be required, there will be more coils, and as the resistance is less there will be less energy lost in the armature, and therefore less heating; as the heat radiating surface is about the same and the velocity greater, the heating will be reduced still more. The field is the same strength as before. If these new proportions do not affect unfavorably the construction and proportions of the frame, they are evidently better than those first determined.

If it is desired to have only one layer, the following proportions suggest themselves: 56 coils of two turns and but one layer will evidently make the diameter twice as large as before with two layers. This would probably make it too large. The number of coils of two turns must either be taken less, say 48, or it must be greater and have but one turn per coil. 72 coils is probably the largest number practical for such a small machine. The diameter of the wire may evidently be less in this case, as the heat is all generated in one layer. Assuming 72 coils, one turn per coil, and a No. 7 B. & S. wire, gives 7½ inches for the diameter of the armature, and a length of over 20 inches. This is undoubtedly too long to be run safely except with a very stiff shaft.

A No. 6 wire gives 8.15 inches for the diameter, and about 17 inches for the length, the induction being assumed to be 1.4, instead of 1.2, on account of the larger diameter or inductor velocity. The resistance of the armature will be about .049 ohms., which is about the same as that of the first form calculated, which had 56 coils of two turns and two layers. The total length of the wire is about 475 feet, as against 615 feet of larger wire in the other form, showing a great saving of wire.

Numerous other proportions could also be tried; those which are best will depend on the nature of the machine, and must be determined in each case by calculation and by the judgment of the designer.

Particular attention should be given to making the field as strong as possible, In general, an increase in the field increases the induction in the same proportion, and decreases the necessary length of the armature in about the same proportion. This enables the diameter of the wire to be diminished, which in turn makes the whole armature smaller and less expensive.

SCIENCE AND THE LABOR QUESTION.

AN ADDRESS BY DR. WERNER SIEMENS OF BERLIN.[1]

THOSE of us who are somewhat advanced in years need but to cast a brief retrospective glance at their youth to perceive the wide gap between then and now. We still remember the time when steamboats and steam carriages made their first feeble attempts at locomotion; when we listened with incredulous wonder to the strange fairy tale that light could reproduce for us in enduring pictures the objects it presents to our eyes; that the mysterious new force, electricity, could transmit messages with lightning speed across whole continents and the oceans which divide them; that this same agent could precipitate metals in a solid form from their solutions, and change night into the light of day! Who marvels now at these familiar things? Our children can barely imagine a civilized existence without them now when, as Reuleaux puts it, every civilized man has several iron servants working for him night and day; when, propelled by the tamed forces of nature, many millions of men are daily brought together who were but yesterday widely separated, and are supplied with immeasurable quantities of goods brought over continents and oceans, through mountains and over their crests and ravines, with a velocity formerly scarcely conceivable; when the world-encompassing telegraph no longer suffices for the needs of intercourse, but must give place to the transmission of oral messages by the telephone, over distances in comparison with which the natural range of the human voice appears as nothing; when the latest fruit of the union of science and technology, electro-mechanics in its rapid development, offers to mankind ever new and immeasurable fields for the investigation and utilization of the natural forces.

The man of science, who more than any other class of men is accustomed to contemplating the phenomena before him, to make deductions regarding the laws which govern them, is concerned not so much with the latest phases of development as with its causes and the laws conditioning these causes. We have before us an obvious law, that of the constant acceleration of the rate of growth of culture. Stages of development which in former ages required centuries for their consummation, and which, at the beginning of our times, still required decades, now complete themselves in years, and frequently present themselves at once in their completeness. This is the natural consequence, on the one hand, of a certain phase of our general progress, the present highly developed system of education, especially in Germany, by means of which the achievements of science, more particularly the scientific methods, have been brought, through the broad channels of the mechanical arts, within the sphere of the every-day activity of the people. On the other hand it is the result of the self-rejuvenating progress in the sciences and arts. And thus we see how in our day each new scientific conception rapidly flies through the whole civilized world, and is caught up by thousands, who seek to utilize it in the most varied fields of industry. It happens at times that apparently insignificant investigations, the surmounting of very slight obstacles which stood in the way of a correct appreciation of the relations of certain phenomena, form the starting point in an entirely unforseen and most important evolution. The accelerated progress thus induced will, therefore, if not arrested by man's own delusions, continue as long as science advances from one higher stage to another. The deeper the insight we obtain into the mysterious workings of nature's forces, the more we are convinced that we are still standing only in the vestibule of science; that an immeasurable field still lies before us, and that it is very questionable whether mankind will ever arrive at a full knowledge of nature. There is no reason for doubting the continuance of the constantly accelerated advance in the fields of science and the arts, unless man himself interposes obstacles to the progress of civilization. But even such hostile activity could effect but temporary suspensions in this advance, at most but a brief and circumscribed retrogression; for the light of science, becoming more and more diffused among all classes and strata of the people, drives back further and further the offspring of ancient darkness—superstition and prejudice—and robs them gradually of their power to arrest the course of development; and the nations who foster and promote science and industry acquire through them such a predominant strength that their subjection by uncivilized peoples and the return of an age of barbarism seem utterly impossible.

But if we are compelled to regard the present progress as incapable of being retarded or arrested, the goal, indeed, must remain hidden towards which this evolution tends. We can, however, determine, from the course of this development, in what way it must modify the hitherto existing conditions in the life of nations. For this purpose we have only to trace the changes already effected. We shall readily perceive that in the age of the reign of science man, by the increased utilization of nature's forces, will be relieved more and more of the severe physical toil which in the struggle for existence oppressed him, and in a great measure still oppresses him; that the labor imposed upon him is to be more and more of an intellectual character, as he will be called upon to guide the labor of his iron servants and not to perform severe labor himself. We perceive further that in the age of science the necessaries and luxuries of life will be obtainable at a much smaller outlay of human labor, so that with fewer hours of labor a much larger share of the produce of labor will fall to each individual. We shall find that the effect of scientific progress upon industrial and commercial activity facilitates more and more the exchange of products between different countries and climes, thus rendering man's life more enjoyable and securing him against the consequences of local scarcity of nature's productions. We see that by the application of scientific methods and mechanical skill to agriculture the soil is made to yield a more bountiful supply of food than heretofore, so that it can support a correspondingly denser population; it even appears probable that chemistry in conjunction with electricity will succeed in producing from the inexhaustible quantities of food-elements everywhere diffused the materials for man's sustenance, and thus render the number of those to be fed independent of the limits of the soil's productiveness.

This increasing facility in procuring the necessaries of life will enable man, by reducing the hours of labor, to devote his superfluous time to his mental improvement and intellectual pleasures; the increased knowledge of the conditions requisite for physical welfare arising from the knowledge of the workings of the forces of nature will contribute to the healthful development, bodily and intellectual, of future generations; the more perfect and more readily manufactured mechanical reproduction of artistic work will secure them admission to the humble cottage, and will bring within reach of all mankind, instead of only the privileged classes, that art which beautifies life and elevates our morals. If we but adhere to the conviction that the spreading light of science effectually combats debasing superstition and destructive fanaticism, we may continue with proud satisfaction in the work of establishing the reign of science, firmly trusting that it will lead mankind towards moral and mental conditions superior to those of the past and present.

This satisfaction, however, has of late been greatly diminished by the gloomy pessimism prevailing not only among the educated, but also among the masses, with regard to the influence exerted by the rapid development of science and the industrial arts on the life of the people,

1. Delivered at the last Congress of German Naturalists, at Berlin. [Translated from the German for the *N. Y. Evening Post*.]

Digitized by Google

as well as with regard to the ultimate outcome of this development.

The question is asked whether mankind is really being made better and happier by all these achievements of science and the industrial arts; whether, on the contrary, these achievements do not lead to the destruction of all our ideals and to coarse sensualism; whether they do not simply tend to aggravate the injustice in the distribution of the goods and joys of this world; whether the improvements in machinery and the consequent division of labor do not diminish the individual laborer's opportunities of independent work, and bring the laboring man into a more dependent position than he has hitherto held; whether, in fact, the supremacy of birth and the sword is not about to be superseded by the still more oppressive reign of inherited or acquired property.

It cannot be denied that this dark view has at the present day a certain plausibility. The rapid and irresistible advance in the useful arts must in its course act destructively on many branches of industry. The improved methods of production frequently have the effect of causing the supply to outrun the demand, and of diminishing the opportunities for labor, inasmuch as the former methods of production which gave employment to much larger numbers of hands are forced to give way in the struggle with the newly invented machinery. The same is the case with regard to the production of food. The cheapened means of transportation supply the older and more civilized countries with vast quantities of the products of distant and thinly peopled regions, whose virgin soil requires no artificial fertilizing, but whose paucity of cultivators has invited the co-operation of labor-saving machinery. The consequent fall in the prices of these products renders it impossible for our old methods of hand-labor cultivation to compete successfully. It is true that improved scientific processes, the more thorough replacement of the constituents taken from the soil, more rational modes of cultivation, afford the means for counteracting these disadvantages; but it is extremely difficult to replace antiquated and untenable conditions and methods with better ones. We, therefore, hear increasing complaints of the general fall in prices and the decreasd demand for labor; and as a means of lessening this evil it is proposed to shut one country against another and to impose forcible checks upon production. The advocates of these theories go so far as to deny the value to mankind of the advance in science and the useful arts, and would even appear to desire a return to the methods of former and, in their eyes, happier times. They, however, fail to reflect that the population of the world would first have to be brought back to the former figures. The number of happy shepherds and hunters which a country can support is very small, and, in estimating the comparative amount of happiness of any given period, the question of numbers must ever remain an important factor. It is a sad but, unfortunately, inevitable law in the life of society, that all transitions, even those to a better stage, are accompanied with suffering. It is, therefore, a humane endeavor to attempt to alleviate these sufferings of the present generation by judiciously guiding and even partially checking the new and irresistible revolution in the conditions of social existence; but it were a hopeless undertaking to arrest or perhaps to force back this current of development. It is bound to continue on the prescribed path, and the countries and peoples which least of all will be visited by its devastations, and be the first to enjoy the benefits of the age of science, will be those which contribute most towards promoting its pacific course. But that this current is urging mankind forward towards a better state, and in its further progress will heal the wounds it has made, is already made manifest in various ways in spite of the unavoidable evils entailed by a transition to new conditions of life.

Does not the mere fact of the general fall in the prices of the necessaries of life and other products of labor, combined with a simultaneous increased consumption and use of these commodities, afford a conclusive proof that the human labor required for their production is not only less arduous, but less in quantity? Does it not prove that the tendency of this progress will be to lessen the amount of time required for earning one's livelihood? Does not the fact that the fall in the price of commodities is not accompanied by a corresponding decrease in the rate of wages indicate an improvement in the lot of the workingmen as science progresses? Greater ease in procuring the necessaries of life is equivalent to an increase in wages. "Higher wages and shorter hours," this ever-growing cry of the so-called working classes is therefore but a manifest result of this progress. For inasmuch as, with the exception of times of financial panic and of transition periods, the quantity of commodities produced is no greater than what is consumed, it must be that the average hours of labor diminish with the increased rapidity and facility of production.

Another very general fact which presents itself is the decrease in the rate of the profits of capital, and to appreciate the importance of this circumstance we must remember that capital—that is, the savings of the wages of labor, as political economists correctly term it—is the gauge of all property. Capital, whether one's own or borrowed, enables a man to avail himself of the use of another man's labor. Were capital really abolished, as some fanatical and deluded people would have it, mankind would have to revert to an uncivilized state, as each individual would then have to rely upon the labor of his own hands for the satisfaction of his wants. But with the growth of capital, that is, the savings of labor, there is no corresponding increase in the demand for its use, inasmuch as the various kinds of apparatus employed for the creation of the products of labor are being constantly perfected, and made simpler and less costly. There is generally, therefore,—leaving out of account fluctuations of transition and violent disturbances—more capital being accumulated than can be profitably invested; or, in other words, there is an "overproduction" of capital, which must show itself, and in fact *does* show itself, in the constant decline in the rate of interest. The savings of former labor, capital, will therefore constantly decline in value as compared with the labor of to-day.

And as for the other, and apparently the weightier ground of complaint of the opponents of our present industrial revolution, which consists in the assertion that through this change the large majority of people are condemned to labor in large factories, and that through the constantly increased division of labor no field is left for the free labor of the individual—herein, too, the natural course of scientific development has its remedy. The necessity for extensive workshops for the cheap production of commodities is at present still due, to a great extent, to the imperfect development of the art of practical mechanics. Till now large machines have worked more cheaply than small ones, besides which the putting up of the latter in the dwellings of laboring men is still attended with great difficulties. But mechanical skill will certainly succeed in removing this impediment to a return to the system of independent, self-sustaining, domiciliary labor, and this will be accomplished by the introduction of cheap labor-saving machinery—the foundation of all industry—into the smaller workshops and the homes of the workingmen. Large numbers of great factories in the hands of rich capitalists, in which the "slaves of labor" eke out their miserable existence—it is not towards this that the age of science is tending, but towards a return to individual labor, or towards the introduction, where circumstances require it, of co-operative workshops conducted by associations of workingmen. Such a system of co-operation, however, can be established on a sound basis only through a more general diffusion of knowledge and culture, and through greater facilities for accumulating capital.

Digitized by Google

Equally unfounded is the complaint that the pursuit of the natural sciences and the unceasing efforts to utilize the forces of nature impel man in the direction of materialism, foster his conceit with regard to his knowledge and powers, and divert him from ideal aspirations.

The more deeply we penetrate into the harmonious workings of nature, governed by eternal, unalterable laws, and yet so completely shrouded from our understanding, the more we are filled with a sense of our humbleness, the narrower appears the range of our knowledge, the more eager are we to extract what we can from this inexhaustible reservoir of knowledge, and the more do we wonder at the all-controlling wisdom which pervades creation. And our admiration and awe excite in us that spirit of investigation, that devoted, pure, and unselfish love of science, which have particularly distinguished the German scholar, and which, we trust, will continue to mark our future generations.

And so let us not permit ourselves to be shaken in our conviction that our activity in investigating and inventing tends to advance man towards a higher stage of civilization, that it ennobles him and fills him with ideal aspirations, that the dawn of the age of science will alleviate his wants and sufferings, increase his enjoyment of life, and make him better, happier, and more contented with his lot. And if we cannot always see clearly before us the path which leads to a better state of things, we shall still adhere to our firm belief that the light of that truth after which we are striving cannot mislead man, and that the power with which it invests him cannot debase him, but must elevate him to a higher level of existence.

REFORMS IN THE PATENT SYSTEM.[1]

BY ARTHUR STEUART.

Mr. President and Gentlemen; Members of the National Electric Light Association:

At the last meeting of the association in Detroit, your committee reported several important reforms that were required in the patent office and in the administration of the patent system. And it was resolved that the committee prepare and present to this meeting bills to be presented to Congress which would provide for the reforms which were considered expedient.

A short review of those reforms may be in place here. The present law of the United States is substantially identical with that passed by Congress in 1836. For half a century we have been working under a law excellent in its general nature and intention, but sorely defective in many of its details.

During the year 1837 there were issued by the United States patent office 435 patents for inventions, while the salaries of the officers employed aggregated $6,850. This was the extent of the business which existed at the time of the passage of this act and for which it was intended to provide.

During the year 1886, there were issued by the patent office 25,619 patents, while the aggregate salaries of the persons employed has reached the sum of $650,000.

A simple comparison of these figures will show at a glance how utterly impossible it is, that a system established fifty years ago for the conduct of a business represented by an issue of 435 patents per annum, and which has been changed only by the addition of greater force as such became necessary, can be suitable for, or cope with, the questions that present themselves daily, in handling so large a mass of business as is now transacted by the office. An average of 448 patents issue every week; more than at the date of the passage of this law were issued in a whole year.

It is easy, therefore, to appreciate how difficulties have arisen that were not contemplated by the commission that prepared this law. Many things have changed in the interval, and while the office has run along with moderate smoothness, the time has come when the importance of the subject demands the attention of Congress. It only remains for those as deeply interested as we are, to knock long and loud at the doors of Congress until we succeed in bringing its attention to the subject.

The last report of the commissioner of patents, filed with Congress only two days ago, points out with definiteness the reforms that are needful.

LABORATORY.

The members of this association, as I mentioned at the Detroit meeting, are most deeply interested in the erection of a laboratory to be devoted in great measure to electrical experiments, for the purpose of testing appliances upon which patents are sought. Scarcely a member of this association who has been before the patent office with an application in this field has not felt the great demand for facilities of this character, and the commissioner urges its importance in his report.

EMPLOYÉS

The nature of the service to the public expected of examiners in the patent office requires that they should be men of such high attainments as to be able to give a thorough and intelligent examination to every invention presented for patent; in order that the rights of the public may be protected and also that a patentee may not be deluded, by being given a patent which, when it comes to be tested in the courts, is found to be worthless. To accomplish this result, it is necessary to pay the examiners salaries high enough to justify good men in making the service of the office a profession, to which they will devote themselves, and expect to make it their life work.

PATENT OFFICE COURT.

I may be pardoned for quoting the commissioner upon the most important subject for your consideration, he says:

"In my last annual report the following statement was made:" "At the present time, in addition to his administrative duties, the commissioner is called upon to hear all cases of appeal from the rejection of a patent by the examiners-in-chief, as well as finally to hear and determine all interference cases which may be appealed to him. Aside from the burden which this imposes upon the head of this office, there is a want of uniformity in the decisions which emanate from time to time from the respective commissioners of patents which ought to be corrected. I know of no better way to correct this evil than the establishment of some tribunal, to consist of at least three judges, whose tenure of office shall be fixed, and to whom all appeals shall lie. I have no doubt that the establishment of such a tribunal with such jurisdiction would not only make it possible for the commissioner to conduct a more successful administration of his office, but would secure to inventors and to the public a much more intelligent and uniform exposition of the law of patents and of the important questions which now of necessity must be determined so hastily.

"I again invite attention to this subject for the purpose of asserting that my experience of the year last past has not only confirmed me in views which I then expressed, but has made much more manifest to me the necessity for some legislation of this character. A court of sufficient dignity and strength ought to be created, and such tribunal might very properly be invested with final jurisdiction in all matters pertaining to the patentability of an alleged invention, as well as all matters of interference between litigating applicants. Such a court with such a jurisdiction would not only result in leaving the commissioner free to attend to the other pressing duties of his office, but

1. Read before the National Electric Light Association, Philadelphia, February 16th, 1887.

Digitized by Google

would inevitably relieve the federal courts of much of the litigation upon these subjects with which they are now burdened."

Here is the deliberate judgment of the man best fitted to judge of the needs of the office and the changes that would accomplish the results desired. A court such as that suggested by the commissioner would have the effect:

First, Of making the practice of the patent office uniform and logical; and those of you who have much business with the office know how great a gain that will be.

Second, It will merge in one tribunal that will never die or go out of office, the decision of all the questions now passed upon by the commissioner of patents, the examiner of interferences, and the board of examiners-in-chief, and, as a result, we may expect to get uniformity and a logical connection in its rulings upon subjects closely related, but now passed upon by several different officers.

Third, The decisions of such a court, if made co-equal with the circuit courts of the United States, would be *res adjudicata* whenever called up in them. Thus relieving those courts of the necessity of examining into questions of patentability when they arise in the trial of patent cases.

Fourth, It might also be well to give this court original jurisdiction, in cases for infringement of patents. Such a court would offer to all those who came before it, the inestimable advantage of a knowledge of, and interest in patents, which would insure to the patentee an intelligent hearing and a disposition to give him all that he was entitled to under his patent.

COMMISSION.

The next question to be considered is, how are these results to be accomplished. It is very difficult as we all know to persuade Congress that the measures that commend themselves to our minds as desirable will either meet with their approval or accomplish the results that others equally as intelligent and interested as ourselves may have in view. I think the commissioner of patents has suggested the proper course when he says in concluding his report:

"I feel so confident that changes and modifications too numerous to be dwelt upon in detail, or to be pointed in this report, of a substantial character which would materially effect the prosperity and usefulness of this entire office, are imperatively needed, that I cannot refrain from concluding by again urging upon congress the necessity of providing in some way, by commission or otherwise, for a complete and exhaustive revision of the entire legislation and probably of the rules which affect this office."

The surest road to the results we have in view would be the appointment of a commission by Congress to examine the whole patent system as it is at present, both the branch under which patents are granted, that is to say, the patent office, and that under which patents are litigated and rights under them determined by the courts; and to report to Congress an act, that will provide for such changes as this commission shall find necessary and desirable. Such a commission created by Congress and appointed by the President could give to the subject a most full and intelligent consideration, and when their report was formulated into an act it would, without doubt, be passed as they prepared it. We could feel that we had a law commensurate with the development of the subject and one that would successfully and satisfactorily cope with it.

I have prepared a bill to be presented to Congress which provides for the creation of such a commission, and it remains with you to adopt it here; and then urge it upon the attention of Congress with sufficient earnestness to secure its passage. The present Congress goes out of existence on the 4th of March, and before that time it must be pushed through both houses if it is to become a law. It is very desirable that this commission should be appointed at this session in order that its report may be submitted to the next Congress.

This bill will be filed at once, and each member of the association is earnestly requested to take the matter up and use all the power at his command to urge its passage upon the members of the Senate and House of Representatives.

PATENTS, TRADE-MARKS AND COPYRIGHTS.

A bill creating a commission to examine and report to Congress needful reforms in the patent system.

Whereas the patent, trade-mark and copyright laws of the United States are deemed to be in such a condition as to require revision, therefore:

Be it exacted by the Senate and House of Representatives of the United States in Congress assembled:

Sec. 1. That a commission be and the same is hereby created, to consist of three suitable persons to be appointed by the President of the United States, who shall hold office until a final report of this commission is submitted to and accepted by Congress. And who shall receive for their services a compensation of $5,000 each, per annum.

Sec. 2. It shall be the duty of this commission to examine thoroughly the present patent, trade-mark and copyright laws of the United States, and those of other countries, and their practical operation and effect in meeting the needs of the public and fulfilling the purposes for which they were created. To formulate a report to be submitted to the next Congress which shall set forth the results of this investigation, and their conclusions therefrom, with reference to changes in, or additions to, the present law, pertaining to patents, trade-marks and copyrights. This report shall also contain a draft of an act which will provide for the changes found necessary by the investigations of the commission.

Sec. 3. The commission is authorized to employ such clerical force as may be necessary for the proper conduct of its work, and to incur such other expenses for stationery, printing, etc., as may be found expedient.

Sec. 4. The salaries of the members of this commission as well as all expenses legitimately incident to its work, shall be paid from the surplus in the United States treasury to the credit of the patent office.

All expenditures by or for said commission, other than the salaries of the members shall, however, be under the control of, and authorized by, the Secretary of the Interior.

INCANDESCENT LIGHTS ON HIGH-TENSION CIRCUITS.[1]

BY JOSEPH WETZLER.

THE demand which the public makes for electric lighting must be satisfied, and although the arc satisfies it to a considerable extent, experience has shown that the incandescent light is in equal demand and that arc light stations are called upon to furnish it. The service is found to be equally as profitable as arc lighting; and hence the introduction, by way of necessity, of incandescent lamps on arc circuits has become quite general.

The object aimed at is to reduce the quantity of copper required for the distribution of the current to incandescent lamps. This is accomplished by increasing the electromotive force employed on the circuit, and reducing correspondingly the total current required.

It is proposed in this paper to give a resumé of the various ways in which this may be carried out, so that those interested in electric lighting may become acquainted with what has already been done and suggested. It will be necessary at the outset to state that it would be injudicious to assume that any one system is given as a perfect solution of the problem, for the conditions of service vary

1. Read before the National Electric Light Association, Philadelphia, February 17th, 1887.

Digitized by Google

so much in each case that where one system would be a success, another might prove a failure. In other words, we must look at the question in a broad light and consider that all of these systems have their field of application, which depends alone on local circumstances.

Very early in the history of electric lighting Mr. Edward Weston proposed the placing of incandescent lamps in multiple series, by means of which they could be connected to a high potential dynamo. He was followed by others who adopted the plan of inserting the incandescent lamps in arc circuits. The usual method of doing this, as you all know, consists in employing a "distributor," which, generally speaking, is a device for connecting incandescent lamps in multiple series on an arc circuit, and which contains mechanism for preventing an increase of current when a lamp breaks. These devices, of which there are several forms in use, among them those of Brush, Slattery, Little-McDonald, etc., need not be more particularly described here, as they are already known to all of you. They are of undoubted value, but they cannot be said wholly to satisfy the general wish of electric light men for maintaining incandescent lamps on high-tension circuits.

The question then arose, How can the field of incandescent lighting be broadened so that the benefits of small-wire circuits can be taken advantage of, and so that the electric light can in the fullest sense take the place of gas as an illuminating agent?

This question can be answered in a variety of ways, each of which may be correct. I will take up the discussion by presenting the most simple case, and that is, the running of incandescent lamps in plain series, similar to the disposition of arc lamps. This has been successfully accomplished in one way, in what is known as the Edison municipal system. If we examine into the conditions under which this system can be operated, it appears that we have here a field which is well worth looking into, and as it has not, to my knowledge, been brought prominently forward, I propose to give a few details of what can be accomplished by it. One of the main objects for which the system was devised is the displacing of the street gas lamps. As such it evidently comprises in itself the use of very long circuits, and their economical operation is a first consideration. The dynamos employed for this service have an E. M. F. of 1,200 volts, which allows for any drop in potential that may be desirable up to 17 per cent. in the wire, while a pressure of 1,000 volts is left to be expended in the lamps. The largest type of dynamo constructed for this system can feed 12 distinct circuits, upon each of which about 65 lamps of 15 c. p. can be placed, or 800 lamps in all. Each of these circuits carries a current of only 4 amperes, so that only a very small wire is required to convey the current, a number being generally employed.

With twelve circuits at our disposal from a single dynamo, it is evident that a wide range of distribution is possible, and the small cost of conductors is a decided advantage. Then, again, the system permits of placing lamps of greatly varying candle-power anywhere in the same circuit, ranging as high as 50 c. p. Thus each circuit is capable of feeding lamps aggregating 1,000 c. p., whatever be the illumination of the individual lamps employed. This gives a basis of calculation upon which definite results can be quickly predicated. The system, such as it has been outlined here, is in operation in various cities, among them Portland, Me., where 500 lamps are so connected; Lawrence, Mass., with 550, and Denver, Col., with 530. While it is principally designed for street lighting, the system is also adapted to interior lighting where the load is a constant one, as in stores which remain lighted up to a fixed hour in the evening.

A system similar to the one described has recently been put in operation by Mr. Chas. Heisler, in St. Louis, and also in Vincennes, Ind.

A recent interesting modification of the method of running incandescent lamps in series has also been brought out by Mr. Alex. Bernstein in England. His method consists in utilizing the full arc current of about 10 amperes as ordinarily employed and running incandescent lamps of low resistance, which require only six volts E. M. F. Thus with an arc dynamo developing 2,000 volts, over 360 lamps could be placed in series. Several installations on this plan have recently been started in England, and with reported good success.

A still more recent method of similar design is that of Prof. Elihu Thomson. This also consists in doing away with distributors and placing incandescent lamps directly in series in the same circuit with arc lamps. These lamps take the full current, and lamps of different candle-power can be inserted in the same circuit. In all these systems, provision must evidently be made, and now is, for preventing the interruption of a circuit when a lamp is extinguished.

There are still other methods of intercalating incandescents on high potential circuits. One of these is by means of induction through what are called secondary generators. As I understand that another member has prepared a paper dealing with this highly important branch I shall leave it with this mere mention and draw your attention to a second method by which induction can be utilized for running incandescent lamps directly on arc circuits. This is the method devised by Mr. Ph. Diehl, which has lately been made public. The incandescent lamps in this system are arranged in two branches, between arc lamps, and a current interrupter is so arranged that the current is alternately broken in one set of lamps and simultaneously sent through the primaries of the other lamps. Thus the main current remains continuous and unbroken, while the rapid interruptions in the incandescent branches induce the current required to bring the filaments to incandescence. Lamps of any desired candle-power can thus be easily inserted in the circuit.

This outline of the principal systems will give electric light men some idea of the various methods by which the incandescent light can be brought into service without the necessity of employing large conductors.

Thus far, I have only alluded to methods where the connection between dynamo and lamp is a direct one, but there are still other methods which come under the title of this paper, but which have hardly yet forced themselves upon the attention of those present. I refer to the use of storage batteries as an adjunct to an electric light station. You will probably all remember that when the storage battery was first brought out prominently, it was said that each house could now be provided with its quota of batteries, which, being charged from a central station during the day time, could furnish current for the lamps in the hours of darkness. During the past few years, while the storage battery has been in a state of slow evolution, this idea has almost fallen into oblivion; but I think the time has arrived when the problem should again be attacked in earnest and be brought to a practical solution. The reliability of the storage battery is now beyond cavil, and it only remains to work out the details. Let us glance for a moment at the method employed here and see what it involves. In the first place, your arc light dynamos, which now lie idle on an average sixteen hours out of the twenty-four, could be run practically during the whole twenty-four hours, charging the batteries in the circuit in the houses during the day time and doing their regular lighting as usual at night. Thus no additional machinery or boilers will be required. Considering the installation in each house, all that would be required would be a battery of accumulators which, for economy of current, should have an E. M. F. of about 60 volts. This would be reached by 30 storage cells, which can be placed on a shelf in the cellar. Such cells, which can now be obtained in the open market, would be capable of furnishing current for 15 lamps, and one charging of 12 hours would, with

Digitized by Google

the ordinary number of hours of lighting, last for 3 days, provided all of the 15 lamps were lighted at the same time. Where the number of lamps is less, the time required for the battery to become discharged would be still further prolonged. A dynamo of 3,000 volts, E. M. F., and having a current of 20 amperes for your purposes, or two arc dynamos, giving each a 10-ampere current, coupled in parallel, would be able to furnish current for 50 houses, each absorbing 60 volts, E. M. F. The conductor required for the purpose need not be greater than a No. 4 B. & S. wire. To make the system perfect, suitable automatic switches can be arranged in each house, which would cut out the battery when the latter is fully charged and throw it into circuit again when discharged. In this manner it is probable that considerably more than 50 houses could be supplied from a 3,000-volt circuit, as not all of the batteries would be exhausted or charging at the same time. Here, then, is one method by which, without a very greatly increased expense, the earning capacity of electric plants can be increased, and I believe the time has come when you should seriously consider the working of the field here presented.

But there is still another way in which the storage battery can be made to do good service for incandescent lighting from arc light stations. As stated before, the dynamos at the station are idle for a large fraction of the day. Now, nothing would be more simple than to charge the storage cells in series at a station during the daytime, and then couple them in quantity, so that they could be connected to incandescent circuits radiating from the central station, which would thus be virtually a secondary battery station. It is a well-established fact that incandescent lamps are not used on an average more than four hours per day, the current required in incandescent circuits during the remaining twenty hours not reaching 15 per cent. of the maximum called for during lighting hours. Let us again take for example a station having only three 40-light dynamos of about 2,000 volts and 10 amperes each. By coupling these in parallel we would obtain a current of 2,000 volts E. M. F., and 30 amperes. This current from 6 A. M. to 4 P. M., or ten hours, could be used to charge a battery of 1,000 storage cells, delivering to each cell 30 amperes for 10 hours; that is, 300 ampere hours. Now, at four o'clock these 1,000 cells which have during the charging been connected in series are changed about so as to be connected in 20 parallel rows of 50 cells each, thus giving an E. M. F. of 100 volts, suitable for incandescent lamps. Each of these twenty rows having a capacity of 300 ampere-hours the entire series of 20 are capable of delivering 6,000 ampere-hours at a potential of 100 volts. Now, if we suppose that with the resistance of the circuit each lamp requires 1 ampere it follows that 6,000 incandescent lamps could be lighted for one hour, or 1,500 for four hours, the maximum average lighting duration established by actual experience. Thus, by the mere addition of 1,000 cells to an arc light station with only three 40-light machines, we could, without the addition of any machinery whatever, by the mere adjunct of the storage battery, furnish current for 1,500 incandescent lamps, and maintain them with the utmost degree of steadiness.

What has just been stated with regard to arc light stations is equally true of incandescent light stations. Instead of having the majority of machines idle during 18 hours out of the twenty-four, a few machines might be run continuously, charging storage batteries which would furnish the supply of current needed during the busy hours.

Such a station, the first of its kind in the world, I believe, is now in course of construction at Haverford, not far from this city of Philadelphia, and I am convinced that the results which will be obtained will justify courageous wisdom on the part of its projectors.

I believe I have shown that those principally interested in arc lighting have a number of paths open to them by which they can with profit add the incandescent light, or for that matter electric motors, to their business. I need only remind them that the street lighting, which most of them are engaged in at present, embraces only 5 per cent. of the total lighting done in this country, and that of the remaining 95 per cent., according to our present knowledge, only 5 per cent. more can be touched by the arc light. The remaining 90 per cent. must be done by incandescent lighting.

POPULAR PREJUDICE AGAINST ELECTRIC LIGHT WIRES.[1]

BY E. R. WEEKS.

THE long line of martyrs to newly discovered facts gives ample proof of the tendency of man to adhere to the old, and fear and reject the new. Even in this nineteenth century of progress, when invention presses on invention, discovery on discovery, the latest and one of the greatest discoveries feels the impulse of doubt and opposition and popular prejudice, the old summation of ignorance cries out against electric lighting.

It is true that the superiority of the illuminating properties of electricity has brought about its use to a remarkable extent, yet the prejudice against the methods of general distribution bids fair not only to hinder its widespread adoption, but to result in legislation, that may retard our industry, or burden it so heavily that the small beginnings upon which we must depend for the general diffusion of electric light, will be prevented by the great cost of construction and maintenance. It behooves us then to inquire into the causes of this prejudice and to discover its remedy.

It must be admitted that there is an element of danger connected with our business. But the same is true of all modern devices that have materially assisted progress. Now that we fully comprehend the power of steam, we can only wonder that its applications met with no more opposition than they did. But every one thought he knew what steam was, while electricity is an unknown, invisible agent, which the popular mind holds in awe, nearly akin to that which led the ancients to propitiate the God of thunder. The element of danger is, therefore, magnified to vast proportions, and this result combined with an utter ignorance of the nature and laws of electricity makes a strong case against a force in regard to which the wisest have much to learn.

To realize the feeling of the public toward this industry, consider our chances as dependent before a jury in an action for damages to life, limb or property. Were the jury chosen even from the average of intelligence instead of from the usual stratum, the chances of a verdict for defendant, would be but one in ten thousand, though all the expert testimony were clearly against the plaintiff.

Again, this element of danger has been increased by careless workmanship and negligent maintenance. Unavoidable ignorance of best methods of managing machinery, running lines, etc., has led to much unsatisfactory service and some loss of life and property, though in an insignificant proportion, when compared with that which attended the early history of gas and steam. But these causes can no longer be pleaded as an ample excuse, for although no system of electric lighting has attained perfection, the safest and most efficient methods of construction are well known, and the poor workmanship seen in the lines in many of our cities, the temporizing resorts and money-saving devices in an industry that needs perfection in all its parts, prove that complaints against us are not wholly without foundation.

Much of the popular prejudice against electric lighting apparatus is the outgrowth of the opposition that this

1. Read before the National Electric Light Association, Philadelphia, February 15th, 1887.

Digitized by Google

branch of electric industry has met with from gas interests, and in quarters from which we had reason to expect a most kindly welcome and considerate treatment. It is true that light wires conveying currents of high tension, or enormous quantity, are not very desirable neighbors for either telephone or telegraph lines, but the commodity they carry is just as valuable to commerce and to the convenience of the public, and has the same right to existence and to accommodation, as have the "great conversers" of the present age. It might seem strange that we have met with such opposition and unkind treatment from our cousins in these kindred industries. Yet from time to time, we find newspaper articles and reportorial interviews with telegraph and telephone men, the reliability and animus of which may be judged by the following extract from an interview with a prominent telephone manager, not many thousand miles from Detroit. "How about electric lights?" "Well that is a different thing. The arc circuit in which the most brilliant lights are placed is a constant danger when the lights are burning. There is present in the wire itself sufficient electricity to kill any man. You don't have to wait for lightning to come along. The lightning is there. Many a lamp trimmer rues the day when he first went into electricity, and the chance for paralysis of the man who handles electric lights are a thousand to one in the case of a man who handles telephones. Yes, there have been a number of fatal cases in that line of business. I knew one man who used to trim the lights on top of the 150 foot mast in Union Square, New York. One day he was trimming the lamps and some people who were watching him saw him topple over and fall to the ground. It was not a mismove, it was a let go. Well the company said he had heart disease, or a fit, but it was just electricity that killed him. I think though that the greatest danger, is in case of a fire. I have known a number of firemen to be knocked down and quite severely hurt at fires by the electricity from the electric light wires. The firemen may be holding the brass nozzle of a hose, and the water may be striking a wire through which a strong current is passing. Presently the wire breaks, or some one turns off the electricity, and the current will run down the stream of water and pass through the body of the firemen, and perhaps seriously injure him. These conditions are not unusual at a fire, and are impossible for a fireman to guard against. It is really far more important that electric light wires should be put underground than either telegraph or telephone wires. It would interfere far less with the former business, than with either of the latter."

Such a tissue of mis-statements and rank ignorance seems to those who know the truth to need no refutation. But the masses have no technical knowledge by which to judge of the utter falsity and absurdity of the whole thing, and, therefore, the result in forming public opinion is highly prejudicial to our interests; for people are willing to have their fears fed by those who will do it.

If these are some of the chief causes that have led to the popular prejudice against electric light lines the remedy is plain. Let there be better construction in putting up poles and in running wires. Let there be a rigorous exclusion of all makeshift devices. Let the entrances to buildings be made in the neatest, most inconspicuous, and above all safest way. Let grounds and crosses be rendered impossible, except under circumstances beyond human control. Maintenance should be looked after with such vigilance that the evils attendant upon the necessary crudity of much of our apparatus be reduced to a minimum. A thorough system of inspection should be instituted in order to quickly detect and correct trouble; complaints from any quarter should be patiently heard, and the causes removed as soon as possible; in other words, by the best construction, by ready, constant and obliging attention, we should seek to render the unavoidable imperfections of service and immaturity of our apparatus less apparent.

One of the most weighty causes of prejudice would be done away with, if a more fraternal spirit among the various electric industries would be created. All should work together for the common good. Each adaptation of electricity has its special needs, which every other is bound to respect, and nothing is gained by attempts to exclude or hamper any one of them. Each is necessary for the present, and each is here to stay. Each has its own weakness which can neither be hidden or cured by attacks on the others.

The members of this association may accomplish much in one direction at least, and that by working for the enlightenment of the general public as to the agent we employ. Only through such enlightenment can we hope for justice, either in the courts or at the bar of public opinion. As people more fully understand the character and usefulness of this force, its channels of operation how perfectly it may be controlled, and the many advantages of its adaptations for lighting, most of the prejudice against it will disappear.

The telegraph and telephone industries have been fully explained to the public in popular treatises; but we have been somewhat remiss in this respect. The promoters of electric lighting have been so occupied in introducing their apparatus that they have confined their writings to technical journals, and have left the instruction of the public to such teachers as the one above quoted.

"FOR HIGH INSULATION."[1]

BY C. C. HASKINS.

In the early days of some new enterprise there is ever a swarming of investigators, as to a newly discovered mine of precious metals or gems, and indecent haste is made to arrive first at the goal. We Americans, perhaps no more than people of the old world, are peculiarly marked with this disposition to thus rush in where angels fear to tread.

In this headlong race some fall early in the action, some faint by the wayside; but a few, masters of the situation, profiting by experience bought, join earnest industry with business capacity, and win by hard knocks and combative endeavor.

In those early days, however, there are errors of commission or omission, having for their object an economy which in the end often becomes an aggravation, if not a positive pecuniary loss.

The electric lighting enterprise has shown to the civilized world that it has firmly planted roots, and has come to stay. It has passed the preliminary skirmishing incidental to the period of infancy; it has made for itself an honorable record as an earnest, brave combatant, and won its way through the lines of its original enemy—the illuminating gas phalanx—which now meekly holds out its hand to proffer the fraternal grip of partnership; and it numbers among its friends leaders in the army of underwriters—a force which, lacking knowledge, either positive or negative, on the subject, would accept no invitations to the christening of the new-born demon of light.

What has wrought this change? Certainly, a dynamic current, having sufficient energy to maintain an electric lamp circuit of any extent, has the same power for mischief to person or property which it had in those baby days of electric lighting, and there are more persons who "can take the current of a twenty-five light dynamo" than there were five or six years ago, for there are more employed in the business. The loud and boisterous element has largely disappeared. There is in its place a cooler determination to find out and apply the why; there is more research; more applications of safeguards to dangerous or weak points. These have supplanted and stamped out the fuss

1. Read before the National Electric Light Association, Philadelphia, February 15th, 1887.

Digitized by Google

and feathers that originally dimmed and befogged the glow and warmth of the grand young enterprise.

The electric light men who are the representatives of the many systems known in this association, while they have, up to the present time, fought the good fight earnestly and successfully, have still to continue the noble work, to bring their enterprise up to the level of callings of equal magnitude in other branches of industry.

While commending and applauding the excellent results thus far attained, I trust I may be permitted to hint at a few possible opportunities which seem to me to point at substantial achievements in the future.

I would modestly, but very positively, suggest that a cheap installation—such a one as we can all call to mind, in some other fellow's territory—an installation which at the commencement called for a very modest amount of money; one in which drawer knobs usurped the place of the glass insulator, put on right end up, out of doors; in which what Miller, of Cincinnati, calls "undertaker's wire," is strung on telephone knobs along the face of buildings; where, to re-enforce the insulation through elevator shafts, under sidewalk crossings, through steam-damp rooms, etc., a wrapping of tape is rubbed down with a lick and a stick, like a postage stamp, to become, as soon as the organic oil has evaporated, of about as much value for the purposes of insulation as a molasses-covered rag; where a dozen similarly ineffectual subterfuges were used by everybody—the present company excepted—that kind of cheap installations are in general the most expensive in the long run, if they manage to live at all.

Better work in the outset is far more satisfactory to patience as well as to pocket, to dynamo man as well as to director.

The use of the wire referred to for outside purposes is a loud-crying evil. In this particular direction but little progress has been made; this relic of the barbarous days of electric lighting still lives.

We, in Chicago, have been accused of having cried wolf when there was no wolf, and afterward, having undergone a change of heart, changed the war cry to something else. Now the facts in the case, I may say in passing, are just this: There was a time when the electric light wires in Chicago were overhead, crossing alleys and streets to some extent, and the cry of wolf was raised. Now the wires, save where they crawl along the fronts of buildings, are out of the way—in conduits, in cables under sidewalks away from probable contact. Now the hue and cry is against other wires on account of their mechanical interference with the firemen. These are all on their way below ground, and when they are down there will be neither "wolf" nor "hue and cry" more.

In a recent paper, by Mr. I. N. Miller, this matter of using inside wire for outside purposes is quite thoroughly canvassed; and I wish to call particular attention to a few facts relative to the insulation of the underwriter's wire when moistened. Mr. Miller says:

"Careful experiments made by immersing 12 inches of this wire in a 6x8 jar filled with water, the ends extending above the jar so that the water would come in contact with the covering only, shows the following insulating properties:

	Ohms.
After 1 minute's time, resistance,	115,000
" 3 " " "	4,170
" 5 " " "	1,770
" 1 hour's " "	280

"One hundred cells of battery were used in making the tests, one pole of the battery being connected with the water in the jar, the other pole with the copper conductor."

I do not believe there is any representative of a well-known electric light system present who considers an insulation of 280 ohms resistance sufficient to protect any unfortunate who grounds the line of a fair-sized arc light circuit through his body at any point in the line; or would like such a wire to rest upon his porch roof, or be on terms of particular intimacy with his telephone apparatus.

Yet there are hundreds of just such lines throughout this country, and they now and then get in their work; and there was a time when the makers professed to, and others did believe—on account of its name principally—that underwriter's wire was perfectly and positively safe from every standpoint of person and property. It was cheap, too, but perhaps that had nothing to do with it.

I am aware that the argument may be used, that if it was so extremely dangerous we should hear from it oftener. My answer to that thought is that if we hear of it at all, as a mischief-maker, we will be doing ourselves, as well as the general public, a great good by so arranging and controlling this matter that we shall never hear from it in that capacity again.

We all thoroughly understand that it is the second ground which does the mischief; but in a well-soaked line of underwriter's wire the second, if not the fortieth leak, is on, and I have seen a case, not in my own bailiwick, where the deductions from rental accounts because of this wet-rag insulation, in one month, would have put kerite wire at every exposed spot, and prevented shutting down for every heavy rain.

Now, the general public when it gets hold of a sensation desires to make the most of it. The newspaper men are no exception. One of the most violent articles on the danger of electric lights I have read was issued by an establishment which was lighted without and within by electricity. The editor wrote it, the printer set it up, the proof-reader read it, and the pressman worked it, all under the electric light; but there was a chance for a sensation; it was out of season for mother-in-law jokes, and the public had to have something. It was a ground hog case. It was a small affair, but it went by telegraph all over the country—an example of what electricity can do.

It knocked a man down. It exasperated or inspired—I never knew which—a newspaper man to write up the story, which was colored as blue as the bluest arc you ever saw, by electric light, and step by step it advanced until the associated press sent it flying, scattering it from ocean to ocean, and from Maine to the Gulf of Mexico by electric telegraph.

This sort of thing is what I think we can, and I feel that we should, prevent. In these comparatively young years of this calling, facts or fancies, either, are trumpeted aloud because they are a new form of sensation; and in some instances these statements have taken such firm hold of communities that the authorities have almost to be dogged into sanctioning electric lights within their corporation limits.

It is better to have the good will of a dog than his enmity; and when other circumstances combine for the interest of the party who is trying to pacify the animal, there may be a double incentive for amicable overtures.

The use of some good form of waterproof wire when it is necessary to run a line along the front of a building to an outside lamp, will add greatly to the general insulation of the line. It may be joined to the inferior wire—which is first-class, on porcelain knobs, for inside work—at a point inside the building where the storm cannot reach. It will cost a little more, but this expenditure will be amply repaid through the maintenance account, and assist in keeping the rental refunding account at a minimum.

There is a deal of very comfortable satisfaction to the electrical department on watch, in the feeling that a rain storm is working no mischief to the plant; that Barkeep's lamps will run till midnight, despite the rain, or that an alarm of fire in the neighborhood has nothing of common origin with the singing dynamo and the little glowing emeralds peeping from under the brushes.

There is comforting assurance in the fact that the danger in handling a live lamp is at a minimum because of good insulation; and there is a growing confidence on the part

Digitized by Google

of the public which reads in its morning paper that somebody, somewhere, was killed by a dynamo current, or that the cause of a conflagration was traced to a wire in some other distant country or town, when that public can point to its own home installations, and say we have never known of an accident here.

The responsible public always demands results. It cares nothing for theories, it must have cold, hard-tempered, crystallized facts, when it comes to matters of business. When these facts are satisfactory the genial public smiles. The smiles of the public are worth money to the electric light fraternity. On the contrary its frowns are irritating and discouraging, while its mutterings and growls are exasperating, if not expensive.

In the old days of fable, somewhere in Wales, if I remember right, there was a race of giants, who, on account of their immense size and strength, had pretty much everything their own way; and to judge of the pictures preserved to us, a pretty rough way it must have been, and at times quite unpleasant to the little people. They rode over, knocked down and dragged out everything in their road, their constant salutation being "get out of the way, or I'll eat you!" As might have been anticipated the race was finally extirpated by the little people, who overpowered them as the Lilliputians did Gulliver. Only one was permitted to live on account of his gentle and harmless disposition, who was recorded as the last and wisest of the giants of Wales.

Electrically speaking, there are little people and there are electrical giants. When one of these giants goes wandering along the street, dodging in at a saloon here or an all-night lodging house there, the little people cringe and shrink as far away from him as possible, but they gnash their teeth and say hard things of the monster. Now and again the huge, hungry creature lets go and drops down to take a bite out of a telephone line, or devours a telegraph switch-board, and shouts "keep out of my way, or I'll eat you."

The telephone affair is a trivial matter intrinsically, and the loss of a switch-board is but a small affair in dollars and cents. But suppose there was a costly edifice consumed or a precious human life sacrificed to the insatiate hunger of the giant. Or suppose, for illustration, the giant were to make a meal of one complete circuit of fire alarm boxes, and deprive an entire district of means by which to call assistance in case of fire. Similar cases have occurred. What then? Would it not have been better otherwise? The public has an excellent memory, and facts like these are stumbling-blocks to progress.

Fortune, in the general distribution of her favors, has seldom made such dispositions of real property as to leave the electric light man entirely independent of the outside public. The unfortunate constructor who is doing his level best to "get there" is often necessitated to ask favors of some purse-proud individual whose life has not unfrequently been made miserable, if not an absolute burden, by the wily telegraph and telephone men, whose ingenuity in whipping the devil round a stump, and getting over, under, through and into a piece of tabooed property, is proverbial. Popular prejudice is against the individual who wears climbers, carries a coil of wire on his arm, or wears a gaudy chaplet of huge porcelain beads.

The quantity of current which is unsafe or the pressure which is dangerous is nothing whatever to the average property owner or the unscientific citizen. Once fixed in his belief that a dynamo current passing his house on a wire ten feet above his roof is dangerous, he feels that he knows what he knows, as well as you can teach him, and yet, on the contrary, if he has been fairly dealt with, and experience has shown that the properly insulated wire has made the current which crosses his premises safe—why, the fellow generally averages up about the same as the rest of mankind.

And there is the insurance man too. He is human, as well; and while in his untutored state he may do a deal of floundering and bucking against electricity in the abstract, experience has shown that he is as ready to receive information, when honestly tendered, as anyone.

Since the last meeting of this association I had the pleasure of preparing and reading a paper before the Western Association of Underwriters, on the subject of electric lighting. While there was a remarkable lack of knowledge on the subject, I did not find the gentlemen unreasonable, but on the contrary, earnest and curious, and anxious to know something of a force of which they had but the most vague ideas; and the thought then occurred to me, that if there were a fraternal exchange of opinion between the two interests, a good fellowship created between the insurance and the electric light people, much good would be the result of the alliance. The two parties are a couple of good fellows who should be well acquainted with each other.

If, as was suggested at the January meeting of the Electrical Club in New York, each of us could capture an insurance man and bring him in to discuss this matter with us—if we could educate them in this matter—I feel certain a strong point would be gained. A timid child will enter and go peacefully to sleep, in a lonely room, if a light is burning, where no persuasion would induce it to venture in the dark; and the insurance agent, no less than the general public, is nervously groping in the dark whenever he discusses the subject of electric illumination.

There is still another incentive, which appeals to the sensitive electric light man's feelings, and argues potently in favor of better average insulation.

You have probably all noticed the different action of the lamps on a central plant circuit, when in the one instance the rag-wrapped wire was well soaked by summer rains, and in another instance the air was crisp and dry in the hard frozen season. The coal-pile, too, feels the effect, and so does the patron.

With the mercury skirmishing for a few hours in the neighborhood of zero, what was nearly no insulation becomes a matter of megohms. All electric wires show this result, from the pigmy telephone and short-distance lines up to the fire-alarm and long telegraph systems. In such weather, during the cold snap in January, direct telegraphing was done, not as an experiment, but as business, between Toronto and Victoria, British Columbia. The frozen conditions of affairs generally along the line conserves to the wire itself all or nearly all the electrical energy which the generator furnishes for the use of the electro-magnets or the chemical solution of the receiving apparatus.

Now, if the tension, the electrical pressure of a telegraph battery, is capable of forcing itself away from a conductor of far more than ample capacity, to escape down a pole to ground during a rain, what are the possibilities to a dynamo current so many times more energetic both as to pressure and quantity, when its route to earth is across half an inch or so of the knob, through a soaked thread wrapping to the wet wood, iron, brick or stone, to which it is made fast at intervals of only a few feet.

A still further reason for high insulation is well illustrated by a recent occurrence in Chicago.

A church edifice there was discovered on fire at about 3 o'clock in the morning. The conflagration was a stubborn one, which, when finally conquered, was explained by the fact of its having been burning some hours, and the fire had worked its way upward pretty much all over the house through the partitions, and the evidence was plain that it occurred immediately under the floor in the basement.

Immediately over the main entrance there was a single arc light on a central plant. The wires to this ran parallel the entire length of the building on the joists within three feet of the hole in the floor.

The fire broke out at three in the morning, and showed that it might have been burning since before the plant was shut down at midnight. No other cause being found, the

Digitized by Google

electric light wires were at once accused of the mischief, and it was only by showing the fact that while the heat had melted off the lead and boiled out the filling of the cable, the wires were all in place on the knobs, unbroken—somewhat disfigured, but still in the ring.

Now, had that fire burned through the floor, three feet farther to the north, no theory would have held water for an instant which denied the assertion made against the electric current.

The cause of the fire is to-day unknown, but electricity was discharged, and declared innocent by the court of inquiry.

I have endeavored to show from several standpoints the necessity, as I contend, for high insulation, and I shall bring this paper to a close by offering for your consideration a suggestion which, while I am aware it is not entirely new, has one feature which I have not met with elsewhere. It is simply this: Provide your superintendent, engineer, inspector, or the proper employé, by whatever name you may call him, with proper reliable instruments for measuring the insulation resistance of your lines. In saying proper instruments, I trust no one will for a moment believe that I mean a magneto. A combination of galvanometer with twenty cells of silver chloride battery in one box and a Wheatstone bridge in another will give you an outfit with which any measuring can be done, from small fractions of an ohm up to over a megohm.

With the apparatus let there be a record book, ruled for date, number of circuit, number of ohms, and a large space for remarks.

Let the measurements be made at least twice a week, or, still better, oftener, and the record made, whether up to or below the standard. In the latter case when the trouble is found, full particulars should be entered in the remarks column.

Now, if a fire occurs where there is any possibility of an electric wire having contributed to the trouble, that dumb witness, if it has been properly kept, will contribute more hard facts to ward off an unjust accusation than could be shown by your president and the entire board of directors in one long, weary day.

ELECTRIC MOTORS.[1]

F. J. SPRAGUE.

I FEEL that I owe you an apology, as I see that it is stated on the programme that I am to read a paper on the transmission of power. The duties, however, which have devolved upon me during the past two or three weeks have been of such a character and demanded so much of my time that it has been simply impossible for me to write a word on the subject in question. What I have to say will therefore be entirely extemporaneous; and if there is a lack of logical sequence in my statements, or I omit any important points, I trust you will excuse me. I may also add that I am almost physically unable to say anything at all, and it is only because I promised Mr. Morrison and some others that I would address you that I have consented to make any remarks.

The time has come for us to look upon the distribution of power in a light altogether different from that in which it was viewed three years or even one year ago. We have heard about electric motors, and we have talked about the possibilities of the transmission of power ever since Pacinotti ran his first motor. But motors were run primarily with batteries, and it is only recently that they have been operated in connection with central stations.

They have been made of small sizes and treated as toys, and more batteries and motors have been invented than there have been made variations in the steam engine, but we have never reached any position from which we could show a commercial return from the use of electric motors until the last year or two.

The distribution of power by electricity, so long looked upon as a visionary and to-be-hoped-for attainment, is now an accomplished fact. It is in its infancy, but it has a future probably second to no other enterprise in the commercial world. It is not necessary here to give a scientific explanation of the operation of a motor. I will try to briefly show that electricity will fill the field in a far more complete and satisfactory manner than, but in very much the same general way as, does the distribution of power from a central station by means of gas, steam, water or compressed air. The use of any of these elements for this purpose is an engineering problem. To be successfully solved, not alone scientifically, but commercially, every part of such system must be in thorough accord with every other part. It is not enough that there shall be a good dynamo, or that there shall be a good motor, but that the dynamos and motors shall be built for certain specific electromotive forces definitely related to each other, and that the conductors should be put in for the distribution of given amounts of energy to the motors, under given losses, and the motors should have an efficiency that is not visionary or sought after, but which is just as well known as the characteristics of any part of the system.

In considering this question, however, we are confronted with grave responsibilities and many difficulties, and those who assume to advise the general public cannot be too careful of their utterances. We have to consider the state of the art and the people's knowledge on the subject. We have to even contend against the ignorance of people in charge of central stations, and we have to contend against a much worse element, the ignorance of the general public concerning electricity. With steam we do not have to deal with this difficulty at all. Trained and experienced engineers can be secured without number. They can be hired by the week or month to care for an engine, and since all engines are based upon nearly the same principles and are practically alike in their operation, no difficulty is experienced in getting good men to care for a five, twenty-five, fifty or a hundred horse-power engine. This is not the case with electric motors. We are obliged to depend upon the central station managers and those whom they especially train.

The practical questions which arise are: Who are to exploit this business? Who are to be actively interested in the extension of this system for the transmission of power?

There are two representative industries already in the field. The first to come was the arc light; then the incandescent light; and now, finally, comes the transmission of power for industrial purposes. There have, in consequence of the order of development of these three different methods of using electricity generated at a central station, arisen three different interests, more or less antagonistic to each other, but which ought to be working in harmony.

No one can doubt that if, ten years ago, the arc light in its present stage of development, the incandescent light in its present perfection, and the electric motor as efficient as it is to-day, were all three at the same time presented to capitalists as commercial investments, all three would have been taken up by the same men on a broad, comprehensive plan, and each would have held its own particular field and would have been pushed with the same energy and success that they have been individually; and that instead of there being more or less of a rivalry between these three branches of industry, they would have been operated under one control, one general expense and one profit.

An illustration of their natural unity of interest is afforded by the action of the various companies representing these different branches. Arc light companies are operating incandescent light; incandescent light companies are running arc circuits; both are beginning to use motors;

1. Address delivered before the National Electric Light Association, Philadelphia, February 16th, 1887.

Digitized by Google

and I suppose some of the future motor companies may be rash enough to supply lights.

But since we have to deal with existing conditions and vested rights and privileges, let us briefly consider the various organizations which can be instrumental in developing this new field of work, and the methods by which they may be successful. As being in the position to actively take up this work, I may mention, first, arc light companies.

A very large number of existing companies have already secured franchises which it would be difficult for other companies to obtain. Some of these companies are to-day just barely meeting their running expenses, because they are supplying power for lights for only a fraction of the day or night in close competition with the gas interests, and perhaps with other electric light companies. As the demand for light varies, of course, at different times of the year, the receipts vary above and below the operating expenses. All through the day, till perhaps five in the afternoon, these stations lie idle. Such companies have their poles erected, their lines run, and certain franchises in their possession, and it would be an easy matter for these same companies to run lines for the distribution of power on the same poles as carry their arc light circuits. The wiring for this purpose would be very simple. In some cases the poles would have to be re-enforced; in others it would not be so. For running these lines to supply power alone, constant potentials as high as 400 volts could be used with perfect safety, and this would very much reduce the size of the wire.

As regards incandescent light stations, many of these run only in the daytime, and do not begin their lighting until late in the afternoon. The bulk of their lighting terminates long before midnight. Other of these stations run during the day because they find the necessity of supplying a few lights in the daytime to get certain contracts for night work, but almost invariably this day work is at a loss. These companies already have their lines run to supply power on constant potential circuits, some overhead and others underground. Since the power would begin in the morning and continue for a general average till the latter part of the afternoon, and then begin to fall off, and the light at the same time begin to come on, such a station, if worked up to its full capacity, ought to have an almost continuous load from morning until late at night; the load consisting first almost entirely of power, then of light and power combined, and finally, almost entirely of light.

The gas engine, although it has made great strides in England, does not stand in high favor to-day in the United States. A gas engine will not work up to the capacity at which it is sold and at which it is nominally rated. It will fall off anywhere from 25 to 50 per cent. below this. Its motion is necessarily irregular and uncertain, because during a large part of its rotation it is dependent upon the inertia of the fly wheel. Such machines are necessarily more costly than electric motors of the same capacity, such cost being about double. They are noisy, they cause a great deal of heat, and they are uncertain. Their advance in England was made before electric motors were as practical as they are to-day, and where gas is sold at a very much lower rate than it will be possible to get it for in the United States for many years to come. The electric motor, then, can easily compete against the gas engine when put side by side, both in initial cost and expense of operation. It is likewise more compact and has an excess capacity, a quality that is never claimed for a gas engine. Gas works have among their residual products coke, which is of very little value. By putting in good generators, running wires for the supply of power alone, and putting the generators and dynamos in charge of the men who are already employed at the gas works, they could produce their power and sell it at a very advantageous price. Their office rent, officials' salaries and attendance would be reduced to a minimum.

Special stations should be put in good manufacturing and industrial districts, and preparations made to supply any demand for power from a half horse-power up to one hundred or more horse-power. There is no possible question that, when a large number of motors are supplied from one district, even when dealing with large powers, electricity can successfully compete against steam.

Double circuits can be used, small powers being supplied at 100 volts and large ones at 400. Such stations should be built to get the steam power at the lowest cost, and hence should have the best engine and the best method of fuel consumption. The district covered will depend upon the location of the station. If this is central, two or four square miles can be easily covered.

I will now consider the different classes of circuits on which motors may be used.

First. Arc light, or constant current circuits, in which the current supplied to the motor is kept constant at a certain number of amperes, ranging from six to nineteen amperes in different systems. The electromotive force at the terminals of the motor varies with the load.

Second. Constant potential, or incandescent light circuits, in which the difference of potential at the terminals of the machines is kept practically constant while the current varies with the load.

Third. Circuits in which the current and the potential both vary, as is the case where there is an appreciable drop or fall of potential on connecting lines somewhat removed from the source of power of a constant potential system.

I am now operating on all classes of these circuits, but since, because of the small ampere capacity of the current on arc light circuits, any large power must require a great difference of potential at the motor terminals, and variations of power will cause sudden and great changes of potential, the arc light circuits have principally been used in conjunction with arc lights for transmission of small powers only, or for constant work.

In considering the transmission of power as an industry, that is, in a broad and comprehensive way, and not as an adjunct to some system of lighting, I may here state that practical and theoretical considerations make it imperative that the constant potential method of distribution is the only safe and feasible one. Since I make this statement, it is incumbent upon me to explain the reasons. The only existing constant current circuits are used primarily for the operation of arc lights. At present, as I have said, these range in capacity from nineteen to six amperes. The unit of light which is required for general purposes necessitates an expenditure of about half a horse-power of electrical energy. A greater expenditure would be extravagant. In order to keep the size of the conductors as small as possible and to allow long extended circuits, the tendency is to reduce the amperes to the smallest number.

The conditions of an arc light probably will not allow this to go below about six amperes; the more ordinary unit is about nine and a half. The commercial conditions unquestionably will not permit, in the future, of a much higher ampere capacity, because the size of the wire varies as the square of the current used. Now with a nine and a half ampere current, a motor to develop one horse-power—supposing it to have an efficiency of eighty per cent.—must have supplied to its terminals 933 watts of electrical energy. In other words, there would be at the terminals of the machine an electromotive force of about 98 volts for each horse-power developed. Suppose, now, we want to transmit one hundred horse-power; it would then be necessary (if the motor be of the same efficiency) to supply to the motor 93.250 watts of electrical energy; and, if it were on this 9½ ampere circuit, we would have an electromotive force of over 9,800 volts.

Now, in practice, arc light circuits vary from, say, 1,000

Digitized by Google

to 2,500 volts. On a 1,000 volt circuit you could recover about ten horse-power; on a 2,500-volt circuit about twenty-five horse-power. In other words, existing arc light machines, if devoted entirely to the transmission of power, are limited to the actual development, on even the largest machines in ordinary use, of twenty-five horse-power; and, if used in combination with light, there would not be available on any particular circuit over a small fraction of this. Now if you are going to consider motors as toys, if you are going to deal with the transmission of the tenth of a horse-power or one-half horse-power, or a one horse-power unit, and are willing to have the element of danger as well enter into these small transmissions, then you can work with an arc light circuit; but if you are going to transmit units of five, ten, fifteen, twenty, or twenty-five horse-power, you cannot deal with the arc-light circuit; it is utterly impossible.

In Boston we have recently put upon certain lines nearly two hundred horse-power. Suppose this were supplied on 9½ ampere circuits. No less than eight circuits of 2,500 volts each would be required, and probably more, because with units as high as fifteen horse-power and this division of circuits, the law of general average could come into play in but a very limited way.

These eight 2,500-volt circuits represent the capacity of a 460 arc lamp station, and to deliver the power not a single lamp could be used at the same time. Does any one really suppose that by this method of working, leaving out for the present all question of danger and unreliability, the same results could be obtained as are in fact to-day? The constant current method of distributing power is the limited and unnatural method; the constant potential, the comprehensive and natural method. This is a fact entirely independent of the question of relative electrical potentials, because on the constant potential circuit we can work at 100, 500, 1,000 or 2,000 volts if we please.

In Boston we at present transmit up to 4,800 feet on a 200-volt circuit.

When dealing with the question of power alone, and with an area of, say, four square miles, the station being near the centre, I would prefer to work with 400 volts. Remember then, that power transmitted means the transference of a given number of watts of energy. It is expressed by two products, quantity and pressure. If one is increased, the other may be reduced. If small conductors are to be used, then it is essential that small currents shall be used, and of necessity high electromotive forces, even when operating on a constant potential circuit.

When dealing with short distances and small powers it is better to use low potentials; but when dealing with large powers and long distances it is absolutely necessary to use high potentials, because the commercial conditions will allow only a certain proportionate investment in copper. There are certain laws to which it is well to call your attention, as they may serve to make more clear some of the questions which come to you.

First, with any given work done by a motor, loss of power on the lines, electromotive force at the terminals of the motor, and distribution, the weight of copper varies as the square of the distance. That is, if the distance is doubled with these given conditions four times the weight of copper will be required.

Second, with the same conditions, the weight will vary inversely as the square of the electromotive force used at the motor. That is, if using double the electromotive force at the motor, it is necessary to use only one-quarter of the weight of wire. Another way of expressing this is, that if the weight of copper is fixed, then, with any given amount of power transmitted and a given loss in distribution, the distance over which the power can be transmitted can be increased in directly the same ratio as is the electromotive force; for example, if a thousand pounds of copper is required to transmit a given amount of power with a given loss, and it is desired to double the distance with the same weight of copper, then the electromotive force must be doubled. Again, with the same cross-section of conductor, the distance over which a given amount of power can be transmitted will vary as the square of the electromotive force. Another way of expressing these laws is by means of a formula which I have been using for a long time, and which you will find of service in determining the size of wire to use in the transmission of power. Let

l = distance between the generating and receiving stations in feet.

n = number of effective horse-power to be delivered on the motor shaft.

E = electromotive force at the terminals of the motor.

v = number of volts fall of potential on the line.

$E + v$ being, of course, the electromotive force at the beginning of the line.

K = efficiency of the motor.

$C\,M$ = circular mils of conductor.

Then, allowing 10.5 ohms as the resistance of a mil-foot of commercial copper, and considering a complete metallic circuit, we have

$$C\,M = \frac{15{,}666 \times n \times l}{E \times v \times K}$$

Let me give you a practical illustration. Suppose we have a motor the efficiency of which is 90 per cent. at 400 volts electromotive force and when developing 10 h. p., and that we wish to transmit this 10 h. p. 5,000 feet from a station, and elect to lose about nine per cent. on the line.

Our initial electromotive force will be 440 volts, and we would have

$$C\,M = \frac{15{,}666 \times 10 \times 5{,}000}{400 \times 40 \times .90};\ \text{or,}$$

$C\,M = 54{,}396$, which is about equal to a No. 4 B. W. G.

This electromotive force of 400 volts is a very good standard. Without serious inconvenience we can go to 600. For long distance special transmission it is necessary to go up to 3,000 or 4,000. If the arc light current be used, all motor handlers take the risk of high potentials.

As I have already said, you have to contend against the ignorance of people using motors. It has been said that you can put a motor on an arc light circuit, and it will take care of itself; that the people at the central station will take care of it. This is true to a certain extent and to an equal extent it is not. I came very near having a serious accident in New York. I was working on a Brush circuit of 2,500 volts. I took hold of the motor and began to adjust the brushes, at first unintentionally and finally intentionally; but it so happened that I was not in a position to be grounded. Had I been so and there had been a ground on the line some distance away, there would have been an end to my motor experiments. A similar end would have resulted if I had lifted the brushes. We put in an automatic cut-out to avoid that danger. We found that a man blocked the cut-out so that it would not work. If that motor and cut-out had any trouble with it (it was on one of the most important Brush circuits in New York, one fifteen miles long) it would have caused the blocking of the entire line.

With a constant potential circuit this kind of trouble is practically impossible. If there are grounds anywhere on the line, or any defects in the motors, they will cut themselves out of circuit automatically, and the rest of the circuit is not affected.

ELECTRIC MOTORS.[1]

BY WM. BAXTER, JR.

THE rapidity with which the electric motor has reached to its present state of perfection is without a parallel in the history of mechanical devices by which energy is derived from the forces of nature. The fact that the energy of gravitation could be utilized through the agency of water from streams descending to a lower level was known to mankind in days pre-historic, and as far back as the days of Archimedes, water wheels more or less perfect were used extensively for industrial purposes; yet, it was not until modern times, when the turbine wheels of the present day were invented, that gravitation motors were brought to a state of perfection. Even to-day, with all the refinements of modern engineering, it is considered a very superior achievement, that a turbine wheel, constructed on the most approved principle, will utilize 90 per cent. of the power in the current that passes through it.

The steam engine (which most people suppose was born in the fertile brain of Jas. Watt) was known and used by the ancient Greeks, although in a very crude form. They utilized the power of steam to impart motion to toys and other unimportant purposes. Through all the centuries that intervened up to about 300 years ago, improvements were unimportant; from that time onward, however, the energy of heat through the agency of steam began to be used extensively for industrial purposes. Steam pumping engines of large proportions were made, and operated in various parts of England, for draining mines; but, as they were very imperfect and costly in operation, they did not displace animal power to any very great extent. Improvements were made, however, from time to time, until Watt, by a masterstroke of his genius, made the improvements which gave to the steam engine a position in the industrial ranks and placed it far *beyond* the competition of animal power.

The steam engine, however, to-day looked upon by most people as a perfect piece of mechanism, is not and can never be as perfect as the electric motor. Not because our knowledge of the laws which govern the action of a steam engine is less than that of the laws which govern the action of an electric motor, but because there is a principle in nature, "the law of latent heat," which renders it impossible for a steam engine to utilize more than a small proportion of the energy of heat contained in steam or the vapor of any other liquid.

From what I have just said, it will be observed that the human race had been familiar with water wheels for at least 4,000 years, and that the steam engine was known in its crude form over 2,000 years ago. The electric motor cannot be said to have been known even in its crudest form, much earlier than 50 years ago: yet, in the short period of its existence it has developed to such an extent that to-day it is as perfect as the best water wheel, *and far more perfect* than a steam engine ever can be. Furthermore, the laws of electrical science, in so far as they relate to the action of an electric motor, are so thoroughly understood that it is possible to obtain as perfect results to-day as are within the limits of possibility. And should the human race inhabit this globe to the end of time, it will never be possible to make a much more perfect motor than can be made to-day.

This statement may appear broad, but I venture to make it and will explain why it is made. To those familiar with the laws of physics, there is no such thing as creating energy. All that can be done is to convert one form of energy into another; a given amount of energy in one form can never be made to give more than an equivalent amount of energy in any other form. To illustrate my meaning more clearly, I will say: An amount of heat energy, the equivalent to 1 h. p. cannot possibly be made to develop more than 1 h. p. of mechanical energy or work, even with a theoretically *perfect* steam engine. And 1 h. p. of electrical energy cannot be made to give more than 1 h. p. of work even with a theoretically perfect motor. It is no more possible to create energy than to create matter. You may take a pound of putty and form it into any shape you please, but it is still one pound. You may roll it into a ball or draw it out into a string, it is the pound of putty still. So is it with energy. You may transform it from heat into electricity, from electricity into molecular or mass motion, and from motion back into heat, but you neither decrease nor increase it. There are many men, however, who do not understand this fact and believe that there is no limit to the power that can be obtained from a given electric current, and that therefore some one may at some future time discover some way by which 100 h. p. or more may be developed from the same amount of current that is now used to develop 1 h. p. Any such result is beyond the limits of possibility or reason.

To-day we develop 9 h. p. from an electrical energy of 10 h. p.; one-tenth of the whole is all that is lost. Therefore, all that the future workers in the field can do is to recover a part of this one-tenth. *They cannot recover all*, because there *must* necessarily be some loss. Therefore, I believe I am within bounds in stating that it will never be possible to make a much more perfect motor than is made to-day.

A theoretically perfect motor would be one that converted all the electric energy passing through it into mechanical energy available outside of the machine. Practically such a result is impossible, for the reason that no mechanism can be made to run without friction, and no electric conductor, no matter how large, can be made without resistance; therefore, there must necessarily be a loss in friction and electrical resistance. This loss can be reduced a great deal, even beyond the point to which it is reduced in the practical motors of to-day. The only thing to limit the point to which these losses can be reduced is the question of expense in construction. A motor can be made to convert nine-tenths of the energy of the electrical current into power without going to any unreasonable expense; but it is doubtful whether the increased cost of construction of conductors necessary to attain a higher result would be compensated for by the additional gain in efficiency.

Now, it may be asked whether the electric motor—inasmuch as it is nearly as perfect as man can make it—has reached a point where it is susceptible of every application which can be made of it at any time. To this, I would answer that it has not; that the applicability of the motor depends upon the cost of generating the current with which it is driven. The cheapest way in which an electric current can be generated at the present day is by the use of large dynamo machines driven by large steam engines of the most approved construction; and inasmuch as the best dynamos must lose something in converting the power of the steam engine into electric energy, and the motor also lose something in converting the electric energy of the current into dynamic energy, the power obtained by the motor must necessarily cost more than that developed by the original engine which generates the current. Nevertheless, as large steam engines are much more economical in their action than small ones and the cost of attendance is less in proportion to their size, it is possible to utilize the current generated by them to develop power in small quantities at a cost low enough to compete with small engines. Up to just what point the cost of power so developed will be cheaper than steam cannot be stated with any degree of accuracy, because it depends upon a great many circumstances. In one locality a motor up to 25 or 30, or perhaps 40 h. p., may be able to compete with a steam engine, whereas in some

1. Read before the National Electric Light Association, Philadelphia, February 16th, 1887.

Digitized by Google

other locality under other conditions, a 5 h. p. motor may barely be able to do it.

If we were to take into consideration the absolute cost of generating power only, then electric motors of a great deal higher power would be able to compete with steam engines. But the electric current will be generated by electric light companies who conduct their business for a profit, and therefore the price which the user of the motors will have to pay for the electric energy he consumes will not be the net cost of developing that energy, but will be that net cost increased by the profit which the electric light company desires to make. But notwithstanding this increased cost, occasioned by the desire of the electric light companies to make a profit, electric motors can compete successfully with steam in point of economy, and when convenience is considered, can compete not only with steam but with any other method now employed for obtaining power in small quantities.

In all large cities and towns people using steam engines rent surplus power to manufacturers in the same building or neighborhood. In a great many cities there are establishments whose business is to run large engines for the purpose of letting out their power in small lots, the price of which is generally low enough to compete with small steam engines, and therefore these prices, as well as the amount of power let in individual cases, can be taken as a guide by electric lighting companies desiring to do business in the same district. If these concerns can make money at the prices fixed, electric lighting companies can make more, for this reason : the loss in transmitting power through shafting and belts is greater than the loss in transmitting it through electric conductors.

In determining the cost of power, to regard simply the amount which is paid for it, is not the only consideration, as many other expenses enter into the question. For instance, the rate of insurance on a building in which the work is of a hazardous nature will be very materially affected by the introduction of a steam boiler. This increase in the rate of insurance must be added to the cost of running a steam engine, in comparing it with the cost of an electric motor to do the same work. Again, in populous cities and in busy portions thereof space is of great value, and the difference in the amount of space which may be used by different kinds of motors employed should also be taken into consideration. Then again, where a manufactory is located on the upper floors of buildings, and the lower part is used for offices or stores, the jar, as well as the noise occasioned by the steam engine, would be such as to make the tenants object to its introduction; and on this account the proprietor of the building would demand a very much greater rent; so that if this rent were added to the cost of the steam engine, it would be found that it would more than make up the difference between the actual or apparent cost and the cost of running the electric motor. Besides the actual expense in dollars and cents, the question of convenience ought to be considered, because sometimes, although there may be no means of determining just what difference convenience may make financially, it is nevertheless apparent to all that it is worth while incurring additional expense, provided a proportionate increase in convenience is obtained. The superiority of an electric motor over the steam engine in point of convenience is noticeable in several points. First, it takes up very much less room, makes much less noise, and is a very clean and simple machine, which does not require a skilled mechanic to keep it in order. It does not have any stuffing boxes that have to be packed from time to time, which are liable to blow out at any time and fill the place with steam; neither does it have any steam pipes, which are likely to burst or spring a leak when least expected. There is no annoyance occasioned by carrying coal or removing ashes; neither is there the liability of injuring the work by soiling it, if the location of the building is such that it is necessary to carry the ashes or coal through a portion of the working rooms in or out of the building. When we come to compare the conveniences of the electric motor with those of hired steam power, we find that it possesses equally great advantages. If a man decides to hire power he must go into some section of the city where power can be obtained. He must content himself with rooms such as he can find. On the other hand, if he buys an electric motor he can select a building in any portion of the city that may suit him, and after finding a building entirely to his liking, can locate the motor therein in any position in which it will be the most convenient, and simply notify the electric light company to introduce the wires. It may occur to some that this is not strictly true, because he may select a building in a location far removed from the electric light mains; but this is altogether unlikely, for the reason that electric light companies run their wires through very nearly all the manufacturing districts of the towns in which they are located, and even if they did not have a wire running through the street in which he might locate himself, they would certainly run so close that they would be perfectly willing to extend their line to his place for the sake of the revenue to be derived from supplying his motor with current.

There is another way in which electric motors can be used, and in which they will be able to compete with steam engines of almost any size, and that is where the power of waterfalls can be utilized to drive the dynamos that generate the current. There are many places throughout the world where vast water-powers within 20 or 30 miles of large business centres are going to waste, where such plants could be established and made very profitable. The distance to which currents generated in this way could be carried profitably would depend very largely upon the extent of water power. If the supply be unlimited, a loss to the company of half the electric energy in transmitting the current to remote places could be afforded, and still furnish it at such price as to monopolize the business of furnishing power. Therefore, it may be said that the distance to which power could be transmitted in this way would range, say, from 10 to 100 miles, or even more.

In the foregoing remarks I have endeavored to show the various ways in which electric motors may be employed at the present time. I have tried to point out the particular uses in which they will be found more economical, convenient, simple, durable and reliable, than any other means heretofore used. In summing up the case I would simply add that the office of the electric motor at the present time is simply to develop power in small quantities, and that it may also be used as a means of utilizing the power of waterfalls that may be within a reasonable distance of large manufacturing centres.

The field which the electric motor can fill at the present day is limited to the cases cited, because we have no means of generating electric energy cheap enough to extend the sphere of its usefulness. The most economic way of generating an electric current at the present day is by the use of dynamo-electric machines, but inasmuch as these machines are driven by steam engines, and there is a loss in generating the current as well as a loss in reconverting it into power, it is simply impossible to generate the energy in the electric motor so economically as in the engine. If we were to use any of the electric batteries now known, the results would not be so good, for the reason that the cost of obtaining the current in this way is yet greater. There are batteries made which are decided improvements in point of economy over the batteries of former years; but they all generate the current by chemical decomposition of zinc, and so long as such means are used the current generated can never be cheap enough to compete with a current

Digitized by Google

generated by a dynamo machine; much less to enable a motor to develop power cheaper than a steam engine. When a battery is invented in which the material consumed by chemical action is sufficiently cheap (say, for example, coal), motors run by the electric energy developed in such batteries will surpass steam engines in point of economy; but until then they never can,

The cost of generating an electric current in a battery can be ascertained with extreme accuracy when the nature and cost of the material used is known. This is owing to the fact that in every case the current is generated by chemical action which takes place in the battery; and this chemical action, which is simply a form of motion, can only be made to develop an amount of electric energy proportional to it. A pound of zinc decomposed in a cell of an electric battery will develop a certain fixed amount of electric energy, regardless of the nature or construction of the battery or of the liquid used in it. Whether the amount of electric energy available from such a battery is more or less than that available from any other battery in which zinc is employed, will depend upon the perfection of its construction. But assuming it to be theoretically perfect, the amount will never exceed that which would be the true dynamo equivalent of the energy due to the electrical action necessary to decompose the zinc. A pound of zinc will not develop as much energy as a pound of coal, and inasmuch as a pound of coal costs a great deal less than a pound of zinc, it will be seen that if a battery could be made to use coal instead of zinc, the cost of generating the current would be so much cheaper as to admit of no comparison. To make such a battery is not an impossibility. It may not be made for years to come, and yet it may be brought to the light of day when we least expect it; but whenever it is made, or whenever a battery is made in which any other substance sufficiently cheap is subjected to chemical action, then the electric motor operated by the current of such batteries will develop power at a much lower cost than it is possible to do it with a steam engine, and it will, therefore, take its place and be the power of the future, while the steam engine will occupy a prominent position in the curiosity halls of science, and will be pointed out to the children of future generations as one of the crude devices used by their benighted ancestors in days gone by.

A SHORT SKETCH OF THE PROGRESS OF ELECTRICAL ENGINEERING IN JAPAN.[1]

I. FUJIOKA, M. E.

My present visit to this country with Mr. Yashima, president of the Tokio Electric Light Co., Japan, is to investigate the different systems of electric lighting and electric transmission of power which are now in actual use here, so that we might introduce to our country the best and most reliable system, and not to make advertisement of our work, if any. I am not well prepared to give you a full and clear sketch of the progress of electrical engineering in our country, and I think this short paper which I have the honor to read now before such a remarkable body of electric men as the National Electric Light Association would be nothing but a curiosity to you.

To begin with the electric telegraph. The first line was put up in 1869, if I remember right, with Breguet's A. B. C. instrument. Since then many improvements were, of course, introduced, and now nearly all the towns, small or large, are electrically connected so that we can telegraph from any part of our country to any part of this country or anywhere else; only it is rather expensive, *i. e.*, about $2.80 per word from Tokio to New York. The instruments we use at present are mostly Siemens' Morse ink writers, and the wires are all overhead except over some wide rivers and straits, where, of course, subterranean cables are used. The Japanese telegraphs are completely under government control.

It was in 1872 that the imperial engineering college was instituted in Tokio, and Prof. W. E. Ayrton, the well-known electrician, now in London, occupied the chair of the professor of telegraph engineering and natural philosophy, and stayed there for six years working in the line of electrical researches with Professor John Perry, then professor of mechanical engineering in the same college. These two gentlemen's names are pretty familiar to you, I imagine, from their valuable labors in relation to electrical engineering and the ammeters and voltmeters of their invention. Mr. Thomas Gray, assistant to Sir W. Thomson, then stayed with us in the college for about three years, and I have been connected with the college for a number of years, attempting to keep up with the progress of electrical applications abroad. I was here in 1884 when the International electrical exhibition was held in this city.

The telephone business is yet quite poor in our country; only the government offices and residences of high authorities are connected. Petitions for permission of organizing telephone companies for exchange systems are made from time to time but the government does not permit it for some reason or other, which I can not tell. I believe, however, it will be permitted sooner or later.

Now, as regards electric lighting, we have the Brush arc lights in some factories, mills and dockyards, and the Edison incandescent lights in some places, and among others may be mentioned 500 lamps in the Osaka cotton mill, and 330 in the imperial military college.

On many occasions, such as at the ball of the minister of foreign affairs department, on His Majesty the Emperor's birthday, November 3rd, at the opening ceremony of the bankers' meeting place and the like, we put up temporary plants with good success, and the result of this together with the most satisfactory reports on the Edison incandescent lighting in the Osaka cotton mill and the *Official Gazette* printing office, induced our people to favor electric lighting with great eagerness. The Tokio Electric light Co., which was organized some time ago, and of which Mr. S. Yashima (now in this room) is the president, has a capital of $200,000, and by the end of this year this capital stock will be doubled. The company has in hand the contract of lighting the new imperial palace with 2,000 incandescent lamps and 100 arc lights from the company's central station, located just outside the palace ground, and from which the current will also be supplied to the residences of the princes and ministers, and other houses around it. It is proposed to place five or more central stations in the city of Tokio, two in Osaka, one in Kioto, two in Nagoya, and in other places. Considering the facts that the city of Tokio is ten miles square, with a population of 1,000,000, and that there is now only one gas company, charging $2.50 per 1,000 cubic feet of gas, and having old fashioned gas furnaces, the Tokio Electric Light Co. has a great deal to do towards the illumination of the city.

In conclusion, as there are many printing offices and small factories all over the city using at present foot power or steam engines ranging from ¼ to 20 h. p., the electro motors will also, without doubt, find good places there. I hope, gentlemen, I shall be able to read a better paper when I see you next time.

1. Read before the National Electric Light Association, Philadelphia, February 17th, 1887.

GLOW LAMPS: THEIR USE AND MANUFACTURE.[1]

BY MAJOR-GENERAL C. E. WEBBER, R. E., C. B.

(Concluded from page 68.)

This gives a little history of the changes of the filament during its life. The tale told may be summarized as

1. Abstract of paper read before the Society of Arts, London (Eng.), Wednesday, December 8th, 1886

Digitized by Google

follows :—That during the first 200 hours the resistance decreases slightly, with consequent increasing brilliancy. These conditions remain nearly stationary for the next 500 hours. After that they alter perceptibly, increasing in resistance and decreasing in brilliancy in a progressive ratio. But it must not be forgotten that the increase in resistance of the filament is not the sole cause of the loss of light. As the filament ages, its original smooth surface roughens, and is consequently increased in area in larger proportions than it would naturally be decreased by the loss of bulk. The larger surface requires more current, whereas the increased resistance is gradually reducing the supply.

Another cause of the loss of light is due to the blackening of the glass by a carbonaceous deposit, which also increases with age. This latter loss in 1,000 hours' consumption amounts, in a good lamp, to 15 per cent. This clouding over of the lamp bulb is due to an internal deposit due to the disintegration of the material, either of the wire mount or of the filament.

Dr. Fleming gave the Physical Society, in 1883 and in 1885, a description of some curious phenomena incidental to this aspect of the use of glow-lamps. It is sufficient to our purpose to mention the cause and the effect.

As time goes on in the life of a glow lamp a smoky deposit is apparently inevitable ; but, quoting Dr. Fleming, "In normal use, when the lamp is not being pressed beyond the E. M. F. at which it is intended to be used, there is a general evaporation of carbon going on from all parts of the loop."

His experiments tended to show that when an excessive temperature is given to the filament by a higher E. M. F., the molecules are projected with violence against the glass, causing by the more rapid disintegration an earlier obscuration of the globe than should arise under normal conditions of consumption. The rate at which the clouding takes place is rapid in the case of some defective filaments. But as a rule makers have conquered this difficulty, and it takes place under conditions which are preventable. The loss of light is very slight, and the appearance of a clouded lamp by daylight is, I think, its most objectionable feature.

Any user of glow lamps on his own installation will find, when he replaces old ones by new, that the latter will give more light, so that, if he introduces a new lamp to replace one which has been broken at a period when most of the lamps are, say, 900 hours old, he will perceive a difference of about two or three candles if he uses 17 c. p. lamps. If the old lamps are, say, 1,700 hours of age, he may find a difference of seven or eight candles. As the current is not economized in proportion to the loss of light, he should recollect that a point may be reached when, by continuing the use of old lamps, there arises an important waste of power. Hence the public should judge of the efficiency of lamps, outside certain limits, more by their constancy of candle-power than by their length of life. Thus the best lamp is that which lives the longest with least variation of light.

Next we may consider the test for vacuum, which in a laboratory can be made with the induction coil as already mentioned by the following test :—Hold the lamp in one hand, and bring the leading in wires in proximity with the pole of a high potential induction coil. If the vacuum is bad, a considerable glow is visible inside the bulb ; if good, the glow decreases, and will be evidenced by the length of the spark between the coil and the wires, so as to be almost invisible, and the spark outside is very faint and short.

The vacuum test may also be made by the measurement of heat, to which a lamp burning for a given time will raise a given volume of water in which it is immersed, but this test has one defect.

Another, but a rougher test, is one which is made by sealing off the lamp with a short length of the vacuum tube attached, and then cutting or breaking its end under mercury, when a bubble denoting the presence of air, if it exists, will be detected as soon as the mercury has risen into the bulb.

The users may make an approximately good test, by observing the presence of luminosity when a lamp is rubbed with the fur of a cat's skin in the dark, or by the touch. The temperature of the external surface of the bulb after it has been alight an hour or so, will show undue heating which will signify the existence of a bad vacuum.

The scientific test of the candle-power of these lamps involves us in the form of photometer to be used, and above all the standard of light. The latter is a question which is still under the consideration of a committee of the British Association. It appears to me that it is not much nearer decision than it was when brought before the congress of electricians, at Paris, in 1882, when the Carcel lamp and the candle still had their supporters ; but there may be members of the committee present who can enlighten us thereon.

For manufacturing purposes it is the practice, as I have shown is done by Dr. Fleming, to use standard glow lamps, which are frequently renewed before they have time to deteriorate. These standards are obtained by photometric comparison with flames or sections of flames of known value ; ultimately referable to an average of a series of tests with the standard sperm candle. But when it comes to competition tests between the lamps of various makers, that which is most relied on is the life test, for although that test is also a trial of the carbon, it is now generally understood that most fairly well constituted filaments will live in a really good vacuum.

To consumers the life test is a matter of economy. They can easily be brought to understand that if their lamps are used with a higher E. M. F. than that for which they were made, over-incandescence takes place, as well as the "clouding" already referred to. This is commonly called "overrunning" lamps, and it is very easily brought about by want of arrangement at the source of the current to secure regulation of the pressure. Often the purchaser of lamps condemns them for their short life, not knowing that all along it is his own fault, and that through frequent over-incandescence, his eye has lost the power to judge, even approximately, of the candle-power he is extracting from them. It is not to be expected that he should have a photometer in his house to check this, but it is not too much to require him to have a voltmeter at a point where he may occasionally test for himself, whether the potential between his mains is dangerous to the endurance of the filaments in his lamps. If, however, his lamps behave as those did as shown in the table already mentioned, he should observe his voltmeter with the view to underrun them in adolescence, so that a healthy maturity and vigorous old age may follow.

There are those present to-night, I believe, who can give the audience very interesting information on these matters.

In some lamps defective cementation of the filament to the wire mount shows itself after a short life by a giving way or a fracture at that point ; but no eye test can, beforehand, detect the liability to this fault. It is said that there is a greater tendency to give way at the junction with the negative metal pole, and from this it has been suggested that when alternate currents are used, their liability to failure would be modified. It will be very instructive if some one of my audience can enlighten us this evening as to the effects on filaments of the use of alternating currents.

Time does not allow of my touching on several points of interest in connection with glow lamps, brought before electricians in late years by Mr. Wilhelm Siemens, of Berlin, by Cruto, of Milan, and by Bernstein in this country.

I trust my audience will realize that my object this evening has not been to enter on too technical or debateable

Digitized by Google

ground, but rather to engage their interest in the subject from its industrial point of view; and that they will also look with approval on my abstention from touching on the patent and legal part of the question, which has so long been, and still is, a matter of controversy.

DISCUSSION.

The chairman (Prof. W. G. Adams, F.R.S.) said General Webber had done well in bringing before the Society of Arts the special points of interest and importance in connection with the use and manufacture of glow lamps. It might not be amiss, as a matter of history, to draw attention to the characteristic curves of different glow lamps, and to the state of knowledge which existed on the subject in 1882, when a complete series of tests were made at the Crystal Palace exhibition. The tests made on this occasion were represented on the diagram on the wall, the curves representing the different incandescent lamps, namely, Swan, Edison, Maxim, the British, and the Brush electric lamps. The candle-power, and watts per candle, were also given. The best result attained at that time was four watts per candle, by two kinds of Swan lamps, the high resistance, and the small eight or ten candle lamp. Next to that came an Edison, which took nearly five watts per candle, and then the others, in the order named. He did not think electricians would approve of the use of earth in place of the insulated wire to the dynamo, as suggested by General Webber. Surely this would be an element of disturbance, and of considerable danger in the case of machines of high potential.

Mr. W. H. Preece, F.R.S., said one of the most important points which had been dwelt upon was the life of the lamp, and the various improvements which had been made during the last few years to secure this extra life, but he did not think they could congratulate themselves upon the longer duration of the lamp. His own complaint was that the lamps were too long-lived. In 500 hours a 16-candle lamp descended to about 8, as a rule; what was wanted was a lamp which would maintain constancy, and there was no mode of attaining this more effective than the use of secondary batteries. It was not possible for any isolated installation to be effective, or complete, unless there were secondary batteries, as had been fully demonstrated in the lighting of the room in which they were now assembled. The amount of money saved in renewing the lamps alone would repay the interest on their cost. With regard to the manufacture of glow-lamps, it could not be denied that this was increasing very fast; only the other day, he heard that at Edison's factory they were turning out about 3,000 a day; and, from a rough estimate which he had made, he found that during the last four years the manufacture had increased so fast that probably, at the present moment, 10,000 lamps were made daily, as compared with 10 a day four years ago. He did not agree with the chairman in his condemnation of the use of earth, nor did he understand General Webber to advocate the use of earth, but only to speak of the use of the return wire in the electrician's meaning of "earth."

Dr. Fleming said an incandescent lamp was not only a useful thing, but it had about it many points of great interest in physics. Many persons had the impression that the interior of a glow-lamp was a place that was empty of all air particles, but this was not the case; it was as full as it well could be. Maxwell had shown that, in a small cube of .00001 inch, there would be found 100 million molecules of ordinary air, so that, in a cubic inch of air, there were a number of molecules represented by 100,000,000,000,000,000. In a Swan lamp, when exhausted to one-millionth of an atmosphere, there remained some 400,000,000,000,000 molecules of air. As it took about ten days to count a million, a simple calculation would show that to count the number of molecules in such a vacuum would take 120,000 years of continual counting. The fact that the glow-lamp was as full of molecules as it well could be led to many interesting consequences. The atoms were, however, so far apart that any one of them could go from one side to the other without coming into collision. In an ordinary glow-lamp, when burning, from all parts of the carbon filament molecules of carbon were being thrown off by the heat, which gradually produced the cloudy appearance that was sometimes seen. If this went on equally, the darkening was equal, but in a glow-lamp the heat was greatest where the resistance was greatest, so that if, by accident, on any part of the filament there was a spot of greater resistance, the scattering of molecules would take place quicker at that part, and the filament would be cut through. The greatest projection of molecules would take place to the parts of the glass which were not shielded by the loop. He held in his hand an Edison glow-lamp, clouded with transparent copper, which had been deposited from the clamps in burning. With regard to testing incandescent lamps, there was no difficulty in making electrical measurements with any degree of accuracy, but what could not be done was to measure the illumination with equal degree of accuracy. The plan of measuring glow lamps by means of candles was a barbarous one, and ought to be got rid of, as a standard candle would vary to any extent up to 20 per cent. Therefore, until they got something more accurate as a standard light, research could not be pushed forward with any degree of accuracy. A suggestion was made at the Paris exhibition to use melting platinum for a standard of illumination, but nothing had as yet been done in this direction. It was probably possible to use as a standard the radiation from a material such as carbon, in which was being wasted, from a definite surface area, a definite quantity of electric energy per second, and, by this method, they would have better means of carrying on the investigation of characteristic curves and the question of illumination. The standard which he used was Siemen's acetate of amyl lamp, which gave very fair results, and, besides this, there was Methven's gas-flame standard, and Harcourt's air gas-flame standard, which gave fairly good results.

Prof. Forbes said that various speakers had touched upon the standard of light, and General Webber had expressed an opinion that they were in the same position as they were several years ago; but upon this he ventured to differ, as he considered they were far ahead of what they were a few years back. The B.A. committee, of which he was secretary, had been carefully studying the subject, and though many thought it was a slow process of elaboration to get a standard from the gradual way in which the committee had been working, yet he believed every one would agree in the end that it was not wise to jump too hastily at a conclusion. Dr. Fleming had said that he thought a standard of light should be produced by electric energy, but there were two difficulties in the way; first, you had to know what was the temperature of your standard; two equal areas of incandescent material might be using up the same electrical energy, and yet the light be totally different; and, in the second place, the whole of the energy being used up was not utilized for the purpose of light. The question was not quite so simple as it appeared, but he hoped that in time such a standard might be obtained, though, at the present moment, the experiments which had been made did not tend to make them hope very much that they would be able to determine, in any convenient manner, the temperature of an incandescent material rendered incandescent by a current of electricity.

Prof. Silvanus Thompson said he happened to know that many improvements had taken place which had not been referred to by General Webber; and in the report of a certain law suit there was reference to a mysterious process called "running on the pump." Whether the processes were universally known, or not, he could not say, but it was quite possible that there might be a few details which had not been revealed in the account of how glow lamps might be made. As a rule it was found when lamps failed,

Digitized by Google

that it was through a fracture of the bridge just above the joint where it was cemented to the wire which led in, but very often the fracture took place not at the heel of the bridge, but just below the crown of the bridge. He should like to know why it was that this occurred; had it anything to do with the bending of the material in the process of formation, or had it anything to do with the distance between the bridge and the surrounding bulb? It had been suggested that electricity possessed a sort of inertia, and did not like to go round a bend, but he could not quite agree with this view, and should be glad of any information upon the point. He considered the use of the word "filament" for the conductor, or bridge, a misnomer, as it was misleading; it should be called a "strip," or a "wire." To give the new name of "filament" to that which was perfectly known before as a carbon wire or carbon strip did not constitute it a new invention, though it might be very clever to invent a new name for an old thing.

Major-General Webber said that, for the exhibition which he had been able to produce that evening, the thanks of the members were due to the directors of the Anglo-American Brush Corporation, who had placed their apparatus at his disposal, and to the officers and assistants of the company for the hearty way in which they had come forward and helped him by showing so accurately and carefully the processes in which they were daily engaged. He thought the warmest thanks of the meeting were due to them, as well as to the worthy chairman.

On the proposition of the chairman, a cordial vote of thanks was passed to Major-General Webber, and to those who had assisted him in carrying out the different processes of manufacture.

PRACTICAL NOTES CONCERNING THE CONSTRUCTION, USE AND MANAGEMENT OF STORAGE BATTERIES.[1]

BY A. RECKENZAUN.

(Continued from page 51.)

In secondary batteries the storage of energy is effected without transmutation, that is to say, the battery receives when being charged an electric current, and gives it out in the same form, the activity of the plates depending entirely upon the electrical energy which has first been expended upon them. In primary batteries, on the other hand, electrical energy is manifested or produced by chemical means; many run-down primary batteries may be re-excited by sending a reverse current through them, when they become secondaries, but then their action is exceedingly limited, because the spent or decomposed acid cannot, by means of this excitement, be changed into its original composition, the limited secondary capability created by such a process of charging being mainly due to the gases occluded in the plates. The true secondary battery is Grove's gas-battery or voltameter, where the evolved gases furnish an electric current direct; it consists of two similar platinum electrodes, one of which is coated or in contact with hydrogen and the other with oxygen. The amount of oxygen which platinum can store or hold in suspension is exceedingly small, the metal itself not being oxidizable, though it has a great affinity for hydrogen. The use and advantage of an oxidizable metal for the purposes of electric storage therefore becomes manifest, and it has been found by Planté that lead plates are easily oxidized, whilst they are capable of retaining their energy for a very long time.

CAPACITY OF STORAGE BATTERIES.

It seems that the energy which can be stored in a secondary battery is really a measure of the amount of oxygen and hydrogen taken up by the plates within the liquid. The liquid in the case of lead accumulators is dilute sulphuric acid. If we place two clean pieces of sheet lead, separated from each other, in a vessel containing acid, and if we send a current through them of sufficient intensity to decompose the liquid into its constituent parts, we then observe that one of the plates will soon be covered with a brownish film. This film is peroxide of lead; the oxygen has combined with the plate which was joined to the positive pole of the charging apparatus, and this plate is commonly called the *positive*. We next disconnect the terminals of the lead plates from those of the generator, and join them to a conductor capable of absorbing the current, placing a galvanometer in the circuit at the same time, in order to measure the current given off; this first discharge will be very feeble and of an extremely short duration, though the charging may have been going on for a long time. The fact is that we have stored oxygen whilst the hydrogen escaped; the negative plate, being clean and smooth, could not retain this gas, the storage of which must be effected by occlusion. If we now reverse the poles of this Planté cell and recharge it, the clean plate will be oxidized, whilst the oxide on the other will be gradually reduced to metallic lead of a porous consistency; the surface is thus no longer smooth, therefore capable of occluding *some* of the hydrogen, and its *capacity* has increased slightly. By many reversals of this kind the lead plates are deeply acted upon, and at last a considerable storage capacity is obtained.

Throughout these notes we shall frequently use the term "active material" in lieu of peroxide, spongy lead, or oxide paste, meaning only those parts of plates which have the power of absorbing the gases given off during electrolysis.

"FORMING."

Planté called his method of preparing lead plates "forming." It was a tedious and expensive process. Faure introduced an important improvement by coating the plates at once, mechanically, with a porous material, a paste of red lead; he obtained thus quickly a considerable storage capacity by merely peroxidizing the material on the positives, and at the same time reducing that on the negatives without any reversals. It really amounted to a thorough charging of the battery, although this first charge is also called "forming," because the oxide paste on the negative plates has to be reduced to metallic (spongy) lead before it can assume its full activity.

Originally, both the positive and the negative plates were pasted with red lead ($Pb_3 O_4$), but it has been found that in the process of "forming" the positive material was peroxidized long before the paste in the negatives could be reduced to spongy lead; hence litharge (Pb O) was substituted for minium in the negative plates, and this being a lower oxide, the requisite deoxidation could be effected with greater economy as regards energy and time. Further experience, however, showed that even with this distribution of different materials, the forming could not be completed at the same time in the negatives as in the positives, so that at last it became customary to form the negatives separately in special boxes containing "blind" positives; the energy expended in reducing litharge to spongy lead is at least twice that required for the peroxidation of red lead. The labor and care which such a double system of "forming" involves is not thrown away; indeed it is necessary for the preservation of the active material in the positive plates, which becomes extremely brittle if subjected to the same length of treatment as that of the negative plates.

RELATION OF STORAGE CAPACITY TO QUANTITY OF ACTIVE MATERIAL.

One ampere of current in doing the work of decomposing acidulated water releases .000158 of a grain of hydrogen, and its chemically equivalent proportion of oxygen per second. "In this action the energy connected to one equivalent H 1 grain, O 8 = water 9, is measurable as 6,840 foot pounds, and the electric conditions represent an

1. From the *Electrical Review*, London.

Digitized by Google

E. M. F. of 1.5 volt." (Sprague, Electricity.) There being a definite relationship established between the current, time and volume of gas liberated, the capacity of an accumulator can best be measured electrically. In practice, for convenience, this capacity is expressed in ampere hours instead of ampere seconds, or coulombs; one ampere hour is equal to 3,600 coulombs. With regard to the amount of active material necessary for the absorption of given quantities of hydrogen and oxygen we find no reliable data suitable for immediate practical application. Chemical equivalents do not assist us, because in practice it is utterly impossible to distribute the materials in such a manner that every atom could do its duty. Gladstone and Tribe have made most elaborate experiments on the relative quantities of the two gases deliberated and fixed with a given current and in a given time, but in their publications we find no exact description as to the weight or volume of lead acted upon. Since a free access of the electrolyte must be advantageous it is perfectly natural to suppose that very thin plates, with a comparatively large surface, will give a greater storage capacity for a given volume of active material than thick plates where diffusion is more difficult. We are, for mechanical reasons, forced to employ plates of a reasonable thickness, and with the aid of examples taken from well-known forms we may arrive at practical conclusions pointing to a maximum useful effect. The following figures bearing upon this question may be useful; the author has deduced these from exhaustive experiments made by him with accumulators of different types supplied by the Electrical Power Storage Co. Weights and dimensions refer to the active material (paste) only, and no account is taken of metallic supports.

(*a.*) *Cell used for locomotive purposes.*

Capacity 150 ampere hours.

Weight of peroxide in positive plates....	6.07 lbs.
" spongy lead in negative plates	5.43 "
Total weight of active material.. ...	11.50 "

The capacity per pound of active material is, therefore, 13 ampere hours.

There are 23 plates in this cell, 11 positives and 12 negatives; the object of the odd number of plates is to have for all the positive plates in a cell two opposing negative surfaces. In each plate the active material consists of 560 small square slabs (square holes filled with paste); the free surface exposed to the electrolyte by these 560 tiny slabs, when counting both sides is 53.7 square inches. The thickness of the positive plates is one-eighth of an inch, and of the negatives three-thirty seconds; the volume of peroxide in the positive plates is thus 36.9 cubic inches, whilst the spongy lead in the negatives occupies 30.23 cubic inches.

(*To be continued.*)

THE HURLBUT FLEXIBLE CONDUIT.

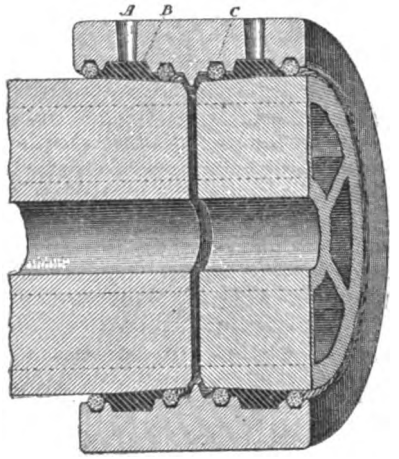
THE illustration below shows a longitudinal section of Hurlbut's flexible joint, for electrical conduits, sewer pipes, etc.

The joints are made with indestructible materials, and it is claimed, will always remain flexible, and hermetically sealed.

The flexible feature of the joints prevents cracking and leaking, from settling of the pipe, which are likely to cause trouble where the joints are fixed or rigid.

The conduit is made of fire-clay thoroughly vitrified and glazed. Its crushing resistance is given as 9,000 lbs per square inch. Clay being a perfectly inert substance causes no corrosion of the insulation of the wires. The nature of the material used and the manner of making and sealing the joints of the pipes and joining to the man-holes are said to secure an entire exclusion of illuminating and earth gases from the system, a most desirable end in any underground system. Water as well as gas being excluded from the system, the cables should remain clean and free from deterioration.

Curved sections of the pipe are made which will be of great practical utility in passing obstructions found in line of the conduit, while building.



C.—Represents Asbestos gaskets, recessed into the coupling, and resting against the pipe.

B.—Is a cavity formed between the gaskets, which is filled with a permanently plastic sealing material.

A.—Represents openings through which the sealing material is poured.

This system is the invention of D. N. Hurlbut and his brother, S. E. Hurlbut, of Chicago, who have patents upon the method of making the joints, and upon the pipe and dies for making the same. Mr. D. N. Hurlbut is also the inventor of an ingenious apparatus for drawing wires and cables into underground conduits. It consists in forcing a needle wire through a curved pipe into the conduit by means of pressure rollers, and attaching a strong rope thereto, and drawing the rope into the duct by withdrawing the needle. The rope is then used to draw the cable into the duct.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

THE PHILADELPHIA MEETING.

THE fifth meeting of the association was held at Philadelphia, February 15th-17th, in the hall of the Union League.

The convention was called to order shortly after noon on February 15th by president Morrison, who addressed the meeting as follows:

Gentlemen of the Convention—Under the resolutions passed at the Detroit meeting, the National Electric Light Association is called in convention in this goodly city of Philadelphia.

The history of the association shows a yearly increase in numbers, in influence and in financial standing. An exhibit of its progress ought to be a source of gratification, not only to those who have devoted their time, their money and their intelligence to this association in Chicago in 1885, but to those who have from time to time come into its ranks to swell its numbers, extend its influence, and strengthen its financial condition. In February, 1885, at the Chicago meeting, 53 companies were represented; at the New York meeting 74 companies were represented; at the Baltimore meeting 102 companies were represented; at Detroit, 124; and to-day our muster rolls bear the names of 159 representative companies gathered from all parts of the Union. At the New York meeting the treasurer reported having received for membership fees $620, and expended $415.67. At the Baltimore meeting the collections amounted to $398.38; the expenditures $537.49, leaving a balance in hand of $860.89. At the Detroit meeting Mr. De Camp presented the report of Mr. Cooper, treasurer of the association, which was to the effect that there was $660 in the treasury, with debts amounting, in round numbers, to $1,200; uncollected dues upon the books, $650. To-day the report of the secretary shows all the bills against the association paid, and a balance on hand of $250.50.

Little or no improvement has been made in either arc or incandescent lighting during the past six months. The attention of investigators has been largely turned in the direction of storage batteries, but on this side of the water little or no progress seems to have been made in that direction. The foreign reports show that storage batteries have been sufficiently perfected to be used both for lighting and power; but in this country, with the exception of an installation of 300 lights in Baltimore, I know of no attempt at any extended lighting from storage batteries up to the present time. Investigation is still being pursued, however,

Digitized by Google

in this direction, and I hope and believe that the next 12 months will, at least to some extent, solve the problem of electric lighting from storage batteries.

Very few accidents have occurred arising from electric lighting plants, when we consider the extent to which the service has grown. The management of the various companies throughout the country have during the last few years paid strict attention to the organization of their construction corps, so that the record for the past year closes up fairly good.

In this city it is to be regretted that, owing to defective workmanship in the running of wires in the Temple theatre, the destruction of the building was attributed by a competent jury to that cause. This case should be written down as a danger signal by which future operations should be guarded from blunders or carelessness which might produce a like disaster. Taking the record of the year, however, we find that fewer accidents have occurred in the electric lighting business than that of almost any other industry employing a like number of men. (The president then read an extract from the paper of Mr. Henry Hine, entitled, "Electricity in its Relation to Insurance," read before the Electric Club of New York recently).

The programme of proceedings was then given, and the president continued:

It is hoped that the convention will so arrange its hours of meeting as to enable every member to be in his place, and contribute his proper share for its information. With so intelligent a body of men it is hardly necessary for me to say that each subject will be considered calmly and dispassionately, without bias and with the best judgment of the members of this association.

The reports of the proceedings of this association are being sought for, not only by all those engaged in the electric lighting business in this country, but many requests from those in England, France and Germany come to us for copies of our proceedings.

With the broad field of the whole world before us, with an audience not confined to those gathered within the walls of this room, but extending over this entire continent, as well as the countries just named, every word should be well weighed, every expression closely guarded, and every meaning clearly expressed before being set forth as the utterance of this association.

One of the subjects which has engrossed the attention of the National Electric Light Association ever since its organization, has been that of underground wires; and in this connection Prof. Plympton, of the Brooklyn Subway Commission, has presented a most exhaustive report of his observations and investigations in Europe. To none would a perfect system of underground wires be more welcome than to the electric light companies, and all eyes are turned toward those cities which are making experiment and investigation in that direction. The ground taken by the electric lighting men throughout the country is that, owing to the vast expense attending the placing of wires underground, they should not be compelled to adopt any ill-digested plan; and that hasty legislation, until such ill-digested plan had passed beyond the bounds of experiment and into the broader field of practical use, would be a great hardship, if it would not seriously cripple the industry which is yet, one may say, almost in its infancy, although 150,000 arc lights are now burning throughout the streets of this Union.

The president then introduced Mr. Thomas Dolan, president of the Philadelphia Brush Electric Light Company, who in turn introduced Col. A. L. Snowden. The latter welcomed the convention to the city of Philadelphia in a very happy manner, and remarked, among other things, that he looked to America for the invention of the perfect storage battery by which electric lighting will be made as universal as it deserves to be.

The report of the secretary was then presented and accepted.

The report of the legal committee was next presented by Mr. Arthur Steuart, who announced that the commissioner of patents, Mr. M. V. Montgomery, had signified his intention of being present.

As the commissioner had not yet arrived, the reading of the report was postponed, and that of the committee on Standard Wire Gauge taken up and read by Mr. A. V. Garratt.

Mr. President and Gentlemen:

Six months ago in Detroit, when on the motion of Mr. DeCamp a committee was appointed to still further investigate and report upon the subject of a wire gauge, the first thing in regard to the new committee which struck me, was that of all the members present at that convention, I was probably the least fitted to act as chairman, and represent the National Electric Light Association before the community in regard to its endeavor to simplify the dire confusion in which the wire gauge question now is.

That conviction has been growing upon me ever since then, and in rendering my report I labor under a certain embarrassment; realizing the large interests involved, and that perhaps if we cannot untie this Gordian knot, we may have to cut it. I shall so far as is possible, lay aside personal opinion and prejudice and voice the opinion of this committee as a whole.

It will be remembered that at the last convention I suggested that perhaps as electric light men use wire chiefly to conduct currents of electricity, a gauge might be devised, the numbers of which should bear a self-evident relation to the resistance of wires of sizes so used, drawn from copper of commercial purity. For example, No. 4 should indicate without any calculation the resistance of a copper wire of that particular size; No. 10 the resistance of that wire, and so on. Although the idea was my own, so far as I know, and I was therefore naturally interested in it, I am frank to confess that after a very careful consideration and much calculating we have been obliged to abandon the idea as utterly impracticable, and right here let me say that if the report I shall make proves to be of any value to this association, much of it will be due to the zeal of my associates—Mr. Slatterly and Mr. Stanley.

Having made up our minds that we were on the wrong track, we retraced our steps, and carefully considered the other gauges now in use in this country to see if by a united effort on the part of the large users of wire some present existing gauge could not be brought into universal use; realizing that even a bad gauge in general use is better than half a dozen good ones in partial use. Without going farther into the matter I will simply say that in the opinion of this committee, there does not seem to be much hope in this direction.

I have carried on a voluminous correspondence with the large makers and users of wires, a part of which was a circular letter which I sent out, on the part of the committee. This circular stated in substance, that a new gauge, based on the decimal division of some standard unit of measure was proposed, and that it was thought best to adopt the ten-thousandth of a meter as the standard of measure, and to adopt a gauge the numbers of which should represent the even ten-thousandths of a meter.

I am pleased to say that a very great many houses, partly indorse our plan. There were however some objections raised, and I will here state the reply of this committee to them, before I say much about the gauge we are to recommend. The objections are as follows:

First, this association has already adopted a gauge. Second, the Brown & Sharpe gauge is good enough. Third, the one-thousandth of an inch is good enough. Fourth, an asymptotic gauge would be the best one to adopt. Fifth, the gauge must be universal, that is adapted to all uses of wire. Sixth, the difference in diameter between consecutive numbers of the metric gauge is too great for electric light purposes. Seventh, why not adopt the Edison gauge which has recently been published?

I think it will not be presuming to say that these questions have suggested themselves to us, and have been discussed long before they were raised as objections by others. It is evident that some of them need no answer at all; in regard to other of these objections I may say a few words to define our position on this question.

Reply to the first objection: "We have already adopted a gauge; namely the English standard."

Out of the many letters we have received, only one voice has raised this objection.

Mr. W. D. Sargent, general manager N. Y. & N. J. Telephone Co., says: "After careful consideration we decided to follow the footsteps of our English brethren and recommended that the Association (National Telephone) adopt the 'standard gauge.'

"This was done after a full discussion at our annual meeting at Providence in 1885.

"I am under the impression that the National Electric Light Association adopted the 'standard gauge' also, and regret to learn from your letter that they think of retracing their steps.

"It is my opinion that the action contemplated in your letter will only defer the universal use of but one gauge and add another to the list of gauges, already too numerous to be worth mentioning."

Without entering into discussion, as to whether we are pushing onward or retracing our steps, as the gentleman would imply, I will simply read from a letter received from a manufacturer not far from here.

Mr. Alfred T. Moore, manufacturer of insulated wire, etc., Philadelphia, writes:

"Some time ago the telephone people adopted a standard gauge, but, so far as our experience has gone, we have but one customer using this gauge, and that is the company that brought it out."

I am also assured by other manufacturers that they have not, since this gauge was adopted two years ago, sold a mile of wire by the English standard gauge, unless it be to this particular customer. The proof of the pudding is in the eating. Therefore, your committee does not recommend the continued recognition of the English standard as the adopted gauge of this association.

Reply to the second objection: "The Brown & Sharpe gauge is good enough." But one voice has been seriously raised to advocate this opinion. Mr. H. B. Thayer, of the Western Electric Company, writes as follows:

"This company would much prefer that no new gauges be

Digitized by Google

originated. We believe the B. & S. best, and we use it exclusively."

We are inclined to agree with Mr. Thayer, in so far that we believe the Brown & Sharpe gauge is the best now in general use in this country, but we also believe that if any one is well qualified to express an opinion on this subject it is Messrs. Brown & Sharpe themselves. I will quote from their letter.

"We believe the 'American Standard Wire Gauge' is the best of its kind in use, because the numbers are in geometric progression. We also believe it folly for English-speaking people longer to adhere to this or any other gauge of its kind."

When the makers and inventors of this gauge admit of their own accord that it has outlived its usefulness, why should we advocate its adoption? Therefore, your committee does not recommend the adoption of the Brown & Sharpe gauge by this association.

Reply to the third objection: "The one-thousandth of the inch is good enough." This is the most serious objection that can be brought against our plan, and I propose to answer it here and now. And in order to do so, I must inquire, is this discussion to establish a unit of measure, or is it to establish a wire gauge? If we are seeking for a unit of measure, by which things of small dimensions may be accurately measured, and fine working machinery constructed, why then I would say with Romeo, "In delay we waste our lights in vain, like lamps by day." But if we are seeking to establish a wire gauge, then the subject merits further discussion.

What is a wire gauge? Obviously it is a series of numbers increasing in regular progression, 8, 4, 5, 6, 7, 8, 9, etc., without any half numbers or any gaps in their regular progression. When applied to the sizes of wire, does the one thousandth of an inch meet these requirements? Most assuredly it does not. Present requirements for electric lights and power purposes call for wires varying from one-thousandth of an inch up to one-half an inch, or 500 one-thousandths. This means five hundred numbers. Ob viously, this is out of the question. Wire makers, especially wire coverers, cannot be expected to carry five hundred sizes of wire in stock, and if they did so, it would be unnecessary. Then it may be said, carry in stock only those thousandths which are most in use, as for example, 204—No. 4, B. & S. G.; 162—No. 6, B. & S. G.; 101—No. 10, B. & S. G., etc. If you do that, your gauge becomes a lot of irregular numbers, very difficult for the expert to remember, for example, a wire much in use is No. 10, B. & S. G. It is 101-thousandth of an inch in diameter. But how is the whole community to remember that? Probably every house in the land, engaged in covering wire has on hand a variety of covered wires of 101-thousandths of an inch in diameter. I doubt if many or even if any of them, have on hand the even number 100-thousandths of an inch, covered and packed ready for the market. It may be said: "But why not settle down to these even numbers, 50, 60, 70, 80, 90, 100, etc.," and let them represent the even thousandths of an inch, and make that our gauge. Instantly the difficulty arises that these numbers vary too much from one another. No. 90 may be too small, and No. 100 may be too large for a specified purpose, and a fraction must be introduced to indicate the size required.

No; from its very nature the thousandth of an inch cannot be converted into a gauge for every day use by the whole wire using community. Large users of wire do order in the thousandths of an inch. They are highly to be commended for so doing. But this is not the question we are here to discuss. If we understand it aright, what is wanted is not a unit of measure, but a wire gauge.

Therefore, your committee does not recommend this association to adopt the thousandths of an inch as its authorized wire gauge.

Reply to the fourth objection: "An asymptotic gauge is the best one." There is but one voice that advocates this idea. Captain O. E. Michaels, U. S. ordinance department.

I quite agree with him, that it would have been gratifying if this association could have consulted with the American Association of Electrical Engineers on this question. It is a broad question, as he has said. The arguments in favor of and against an "asymptotic" gauge are many. I do not propose to enter upon them here.

Their intelligent discussion would have to assume a familiarity with conic sections and the calculus, and I fear we should be using valuable time without getting much nearer the object of this discussion. I think you will all agree with me, that to attempt to get the American wire users as a class of men to adopt a wire gauge, the comprehension of which presumes a working familiarity with the higher mathematics, and whose very name must ever be a stumbling block to the ordinary mechanic, is an undertaking that we well may shrink from.

This must not be construed into a reflection upon the intelligence of this association. It is simply a frank admission that we do not care to discuss fine mathematical questions in business hours. Therefore, your committee does not recommend this association to consider the adoption of an asymptotic gauge.

Reply to the fifth objection: "The gauge must be universal," I have conversed with large wire makers, and from them I gathered that it was almost out of the question to hope for anything like co-operation from trades other than our own. In the thousand and one uses to which wire is put, the question of gauge is trifling compared with our own case. The makers of pins, or barbed wire fence will not and cannot be expected to take a very lively interest in the way we measure our wire. To the telephone and telegraph people, a particular gauge is more a matter of convenience than a dire necessity, as in our case. Therefore, this committee does not recommend this association to wait for co-operation.

Reply to the sixth objection: "The numbers of the proposed metric gauge vary too much." That is, consecutive numbers are too far apart as to size, and in practical work, one number may be found too large, and the next number too small. I shall answer this objection with a few electrical figures, which shall enable us to determine if it is really so.

As the variation in diameter increases in regular arithmetical progression, the difference in size is of course more marked between the small numbers, than it is between the large sizes. I shall, therefore, seek my illustration from rather small sizes of wire, because in regard to these the objection is more pertinent. No. 14, B. & S. G. is a rather small number, which is much in use by electric light people, in fact it corresponds very closely in size to the smallest number in the new Edison standard gauge, in a published account of which is a statement, that this is "the smallest found to be mechanically and electrically efficient in the equipment of buildings with Edison conductors." Therefore, it is appropriate to bring the objection against this particular size. The difference is conductively between No. 14 B. & S. G. and its next largest size No. 13, is about 30 per cent. of its total conductivity. The difference in conductivity between corresponding numbers of the English standard, Stubs, and the old London gauge, is not far from the figure I have stated. The corresponding number in the Edison standard gauge, varies in conductivity from the next number by 40 per cent. The corresponding number in the gauge which your committee is about to recommend, and against which the objection has been brought varies in conductivity from its next larger number by only 16 per cent. In view of these figures your committee does not recommend this association to recognize this objection as valid against the metric gauge.

Reply to the seventh and last objection: "Why not adopt the Edison standard gauge, which has recently been published?"

Replying to this objection places your committee in an embarrassing position. We trust that you will recognize the delicacy of our position, and not oblige us to discuss this gauge. A large and powerful company has seen fit to publish a system of wire measuring, which it has found convenient for its own particular uses; it has attached its own name, and now publishes it as a candidate among the other gauges now striving for national adoption. This is too broad a question to be treated in this way. Personally I opine, and I voice your committee in this statement, that the gauge which eventually comes into general use, will not be the Brush gauge, nor the Edison gauge, nor the Thomson & Houston gauge, nor any one else's gauge. It will have to be a national gauge, independent of any particular system of lighting, or any particular company's name or patronage. Any action contrary to this, would be contrary to the very spirit of this association. Realizing that there are elements of danger in the national adoption of this gauge, and not seeing merit enough in it to warrant its general use, your committee does not recommend this association to adopt the Edison company's gauge as its recognized standard.

The gauge which we do recommend, I will briefly describe, but will not defend, knowing right well that it needs no defense. You will remember that the chairman of your committee on wire gauge last year closed his argument by reading a letter from Mr. F. R. Welles, of Antwerp, in which a metric gauge was suggested, and the statement made that generally throughout the continent of Europe wire was designated by a fraction or multiple of a millemeter. Mr. Pope had the foresight himself to predict that soon the same idea would take hold of the minds of men on this side of the Atlantic.

Your committee has worked the matter into shape, and the proposed gauge may be described as follows. A series of numbers from one to one hundred, to represent tenths of millemeters, that is No. 1 to equal $\frac{1}{10}$ millemeter, and No. 2 to equal $\frac{2}{10}$ millemeter, and so on. No. 1 will be about the size of No. 38 B. & S. gauge, and No. 100 will be about the size of No. 000 B. & S. gauge. The sizes of the wire will vary about the right amount for electric light purposes. They will possess this property; the conductivities of the wires varying directly as the squares of their diameters. Any workman can at once tell that No. 8 has 16 times the conductivity of No. 2 without referring to any table. I need not argue the advantages of such a gauge. Then again, the gauge unit would be of the same system, as that underlying the ordinary units of electrical measure. The volt is a metric unit. So it is with the dyne, the erg, the watt, the coulomb, the ampere, the farad, and the ohm. These are units that electricians use in their daily work. They are all based on the metric system. What stronger argument than this can be brought?

Digitized by Google

Your committee would then respectfully make the following report:

To the National Electric Light Association, assembled in convention, February 15th, 1887.

GENTLEMEN:

Your committee on wire gauge report that after a careful consideration of the whole subject they recommend as follows:

1st. That the British (so-called) standard no longer be recognized as the gauge of this association.

2d. That a series of numbers from one to one hundred, each number representing the tenth of a millemeter, be adopted as a gauge, in conformity with general use in continental Europe. This gauge will cover all numbers from 38 to 000 B. & S.

3d. That this gauge come into effect in six months from the present writing, or at the next convention of this association.

4th. That it be called the National Electric Gauge.

5th. That a committee be appointed to properly tabulate this gauge, working out columns of figures representing the sectional area in thousandths of a millemeter; the sectional area in thousandths of an inch; the ohms per thousand feet; the pounds per thousand feet; the ohms per foot; the nearest corresponding number on Brown & Sharpe's gauge, and other information such as shall seem best.

6th. That this committee having taken all reasonable precaution to insure the accuracy of their figures, have the table electrotyped, and a copy sent to every wire maker in the country, with the request that he publish it in his circular and price-list, and mail a copy to his customers on the first day of next July.

7th. That the members of this association pledge themselves to purchase of a reputable gauge maker, on or before the next convention of this association, a gauge or micrometer, reading in the numbers of the National Electric Gauge, at a cost not greater than that of gauges and micrometers now made to measure in the thousandths of an inch.

8th. That the members of this association offer to the committee so appointed their hearty encouragement in this not easy undertaking. Yours very respectfully,

MARMADUKE M. M. SLATTERY,
ALLAN V. GARRATT,
HENRY V. STANLEY.

Personally I would add but a word. Let us look at this question seriously, gentlemen, and not rise from this session, without having taken some decisive action.

Let us no longer oblige our working electricians to use a crooked yard stick of no particular length.

DISCUSSION OF WIRE GAUGE REPORT.

Dr. Moses—I am delighted to see that the matter has been referred to competent persons for consideration, and that they have embodied their ideas in such an elaborate and correct report. However, while making this change, let us be quite sure this time that we are getting something that is on the basis on which we want to calculate, that is, the resistance. That is the only element the electrician has to consider in regard to his wire. Let it be something that is interchangeable with everything else that is adopted as a scientific standard in electrical measurement. The centimetre-gramme-second is taken as the basis now of all calculations. Therefore, we should have a fraction of a centimetre as a measure. But let us rather consider length than cross-section; that is to say, if we take a unit of length—the metre or the millimetre, or what not—let it be a unit of length commensurate with those units that are now adopted, and we can then interchange every time without the frequent use of the extraction of the square root. As that is a matter which will require some deliberation, I think it would be well to refer this report for speedy action to the executive committee, who might act upon it. It is a step in the right direction. Now let us march on in the same direction.

The President—The committee has shown so much intelligence in its treatment of this subject, the report is so explicit and so straight, that it seems to me that it is the first committee that has fully discharged the duty imposed upon it by the association. It has convinced me that the first step to be taken is to undo the work which was done at the Baltimore convention; that leaves the field clear. The next thing is to continue this committee, add to it perhaps some more gentlemen, and then when the report goes out, members can read it and come to the next meeting fully prepared to discuss the question. Referring to the first recommendation of the committee, that the British standard no longer be recognized as the gauge of this association, the report of a committee recommendiug the adoption of the British standard was adopted. Now let us see if they have adopted it. Is there a man on this floor who has carried that out in practice? If he has, let us look at him. The reason why they did not do it is that it does not fill the bill. In the shops of the concern that I am connected with in Baltimore the wires have been ordered by thousandths of an inch. I believe that that is the best system in use to-day. If a better one is provided—and I believe this is a better one—then I will guarantee—I am speaking for myself, not the association—that we will drop the thousandths of an inch and accept the standard gauge. If the sixth recommendation of the report be carried out, it wil go a long way toward making this the universal gauge, because the place to start this business is with the manufacturer. If you get the body of wire manufacturers in this country to adopt a successful method of measuring the wire, and if they do what is laid out in that report—send out to the wire users this gauge together with an explanation of why it has been adopted—there is not one man in a thousand who will cavil at its adoption. We have never before had the ground to go upon so clearly defined and backed up by so cogent reasoning as in this report. So, in my mind, if you adopt this report and add two members to the committee, at the next meeting those who will find reasons to disagree with the report will have ample opportunity on the floor to undo anything which has been done, or suggest remedies for and defects which might occur to them in this matter.

Mr. Garratt—It occurs to me, in view of what you have said, that it would be wise to strike out that paragraph of my report in which it is suggested to authorize an electrotype of this new gauge and distribute it; and in its place I would suggest that the committee which may be appointed be authorized to print a hundred or two copies, and mail them to the leading wire users of the country, instead of going to the expense of having an electrotype made.

Mr. L. H. Weissleder said that it would be unfair to the committee to adopt this report, and then at the next semi-annual meeting have the chairman ask how many have adopted this gauge, and it would, therefore, be a good plan to have all the electric light companies pledge themselves to adopt this after a reasonable length of time, and in the meantime familiarize themselves with the new gauge, and the relation of the new to the old which they have discarded, and let the transition be gradual.

Mr. Eustis—I want to call attention to one thing in regard to wires, and that is that in the drawing of the fine sizes there is a film formed on the outside of the wire. Now, the resistance of that film may be different from the resistance of the core. Therefore, when you take any gauge which is measured on the diameter—which, I think, is the best way to measure it—your resistance, as so tabulated, is not accurate for the smaller wires. Another point I wanted to speak about is the difference between the British Association ohm and the legal ohm, as we have it here. There is quite a difference between the two. Another question is, getting the weight per mile of wire. For the unit of specific gravity we take exactly a cubic foot of water. I have found great difficulty in getting hold of the best authority for the determination of the weight of a cubic foot of water, and also the specific gravity of copper wire. The best authorities I have found seem to point to a specific gravity of $8\frac{9}{10}$. Some of the old tables were based on 8.879, although so much smaller; so that would be a point which ought to be determined, I think, before any definite standard is taken in regard to the weights.

Mr. Garratt—I intentionally left out of my report and my paper all considerations of the kind suggested, because I think the place for the discussion of those subjects is at the sessions of the committee. This is a business association, not a scientific body. Scientific questions are to be discussed by scientific people in their own meetings.

The President—Still, a reference by any member to such a subject can be carried away and used for the information of the committee. The suggestion made by Mr. Eustis is, I think, a very valuable one.

On motion of Mr. J. A. Powers, of Troy, it was agreed that four members should be added to the committee, and the president then appointed Messrs. Moses, Weeks, Keilholtz, and Eustis, in addition to the old committee, Messrs. Garratt, Slattery, and Stanley.

Mr. C. C. Haskins then read a paper entitled "For High Insulation." (See page 93.)

The discussion of Mr. Haskins' paper was postponed until after the recess, which was taken till 4 o'clock.

TUESDAY AFTERNOON SESSION.

On re-assembling at 4 o'clock the discussion of Mr. C. C. Haskins' paper was taken up.

Mr. F. A. Mason—In conversation with insurance inspectors I am continually met by questions of this sort: "We do not know much about wires or about insulation, and we want to know something, and we wish that there were something authoritative we could lean on. We cannot examine different insulations, we only guess at what is the proper insulation for us to pass." It would seem to me that this is the place and that this is the time for some authoritative statement to be made, and without following with any remarks of my own I wish to offer the following resolution:

Resolved, That a commission of five members of the National Electric Light Association be appointed whose duty shall be:

Digitized by Google

First. To determine what qualities are essential to good insulation for electric light wires.

Second. To examine such insulation as may be submitted to it and to determine in what degrees the different insulations submitted possess the virtues required.

Third. To report at the next meeting of the association the results of their investigation.

Mr. Steuart—I hope that these resolutions will be adopted, and a committee will be appointed to consider this question. It is one of the most important subjects connected with electric lighting that we have to deal with, as I had the honor to point out at the Detroit meeting as chairman of the legal committee. It has a very important bearing in consequence of the fact that the relations which exist between electric light companies and the public, and between electric light companies and insurance companies, are almost entirely due to the condition of these wires. The legal question as to whether an electric light company is responsible for the damage caused by fire or the damage caused by the loss of life, will be dependent upon the answer to this very question when a case comes to be tried for such an accident, should it occur, and the companies were to be brought into court under it. The condition of the wires will determine the question of the responsibility of the company, and if it be thoroughly proven that it was within the power of the company to have their wires in a perfectly good and safe condition, and it be further proven that they were not in that condition, and that the accident resulted from that cause, the electric light companies will be held in damages, and be made to pay them. Whether it be a loss from fire, or whether it be a loss of life, they will be held responsible for the damages, and they should be. Therefore, I think it is a very important matter for this committee to be appointed, and that this association should take broad and decided ground with reference to the character of the insulation, the insulators that should be used by its members, as well as by those who are outside. Give the insurance companies and give the public to understand that this association has taken a stand before them in which they pretend to say, and propose to say, that they are giving to it the right thing and that they are going to give the members the opportunity of having a committee determine whether they are doing the right thing. Then it will stand in a proper position before the public, and they will gain the confidence of the public. For that reason I think this committee should be appointed, and I think it will be.

Prof. Houston—I was not present at the meeting this morning when the paper under discussion was read. I simply rise to ask whether the discussion related entirely to the subject of insulation? It seems to me that an electric light wire to be safe should possess three properties. Unfortunately, the three properties would be very difficult to be found associated together in the same wire. It should not only possess high insulation, but it should be impervious to water or moisture, and should be incombustible. Whether or not these properties can all be found in one and the same conductor I am unable to say, but when the conductor is found that possesses this three-fold group of properties, I am sure the best conductor will be found for economy and safety in working. I simply rose to ask the question whether under the head of insulating power the other two equally important requisites, impermeability to water and incombustibility have been considered?

Mr. L. H. Weissleder—Before the subject shall receive the sanction of this association there should be an amendment. I think it would be a good thing to have it qualified, as under some circumstances there would be a great loss entailed in the rearrangement of wires and great loss to property, amounting to the confiscation of some plants running on a very small margin. And another thing; the gentleman who has just preceded me was speaking about insulators and a fire-proof covering at the same time. I might say that a wire thoroughly insulated does not affect the ground line or produce fire, because the fires produced have generally been in wet weather, and we have found in our own business in running into buildings, that sometimes the current would escape from the wet wood and produce a little conflagration and some damage. A great many complaints have arisen from this. A good many companies are equipped with good wires for ordinary weather, but if the wire were run against the iron cornice or a roof it might produce an escape and be unsafe to property, and manifestly a fire might occur.

Prof. Houston—It is true that a wire well insulated originally may from moisture become a source of danger from fire, and might not be the cause of fire itself. But it is not true that the wire is free from danger as an incendiary; that is, the covering acting as an incendiary. A very serious fire is likely to occur on the outside of the wire itself. Surely, in a practical meeting like this, it must be well known to members that there are wires which, if inclined upward a little and touched at one end by a match, will shoot forth a column of flame almost as rapidly as a man can walk; there comes the danger. When my duties led me to inspect the circuits at the International electrical exhibition, of which I was the electrician, I remember very distinctly that we had to guard very carefully against wires of a readily ignitable type, and many a time have I tested wires from which the flame would run from one end to the other almost as rapidly as a man would walk. The trouble with such wire would be less in danger from the current which traverses it than in carrying fire from one part of the building to another.

Mr. Callender—I move as an amendment to the resolution that the first and third objects be kept in view, and that the second be left out. It seems to me that the object of the committee should be to investigate the question of what insulation is necessary, and that it should not be to determine what kind of insulator should be used, any more than a committee should be appointed to examine into which kind of dynamo is best, or which kind of lamp should be used. The object of the inquiry is one of very great importance, and its importance is growing day by day and being recognized by electric light companies; if the second part be left out, it seems to me the resolution would then cover all the points that should be investigated by this association.

Mr. Mason—I introduced these resolutions at the suggestion of a number of insurance inspectors, who said that they were not able to determine these questions; they had not time to investigate; they were obliged to pass upon installations; they were obliged to say whether they would or would not pass and use certain wires, and it seems to me that it does lie in the purview of this association to determine what are the needed qualities in the first place. I do not need to go on and mention that there are other qualities not in the way in a good insulation, but the gentleman who spoke a few moments ago on the legal aspects of the question made a very comprehensive point. Those of us who own installations and who are connected with electric light companies wish to be protected and we are not protected to-day. I have the misfortune to be connected not alone with an electric lighting company, but also with a wire interest; but I speak now in connection with the first interest. We want to know whether we are protected against suits from telephone and telegraph companies and from private individuals if we have taken all due pains and precautions.

On being put to a vote Mr. Callender's amendment was lost and the original resolution carried.

The committee of five provided for in the resolution was then appointed by the chair, as follows: Prof. E. J. Houston, M. M. Garver, R. T. Robinson, Carl Hering, and Prof. W. D. Marks.

Mr. E. R. Weeks then read a paper on "Popular Prejudice Against Electric Light Wires." (See page 92.)

DISCUSSION.

The President—While Mr. Weeks was reading his paper, this question occurred to me. What makes cheap work possible? Two things, sharp competition and bad pay. When you put in the field in competition three or four electric lighting companies, instead of endeavoring to bring about a good service which will pay a fair profit, an effort is made in the direction of obtaining the contract at any price almost, whether there be profit in it or not. Now, what is the result? All this follows that Mr. Haskins suggests. Among well ordered electric light companies you will find that the cost of installation is much higher than those where helter-skelter methods were adopted in the early days of the business. They make the electric lights at the cost of 40 cents, and they are compelled to serve corporations because corporations will have electric lights. It has passed now beyond the point of experiment; it is recognized that electric lighting is the only method by which streets can be properly lighted; and the corporation seeks to get the lowest price without going into an intelligent examination of the details by which the company shall accomplish that lighting. Therefore, the company will offer to light the streets for 54 cents, and I think that they have offered lower than that when they knew, and we know, that it is impossible for them to make and deliver the light at 54 cents and receive any profit therefrom.

Not only do they lose the business themselves, but by this sort of competition they injure the business and the interest of the electric lighting companies who put up the capital and enter the business as a bona-fide industry in that locality. Now, there is a disease; I do not know the remedy. We have endeavored to apply it at every association meeting. So far as I have been able to see and recognize it, I have not only used this organization but other organizations to prevent this sort of work where I have been interested. The demand for cheap shoes gives rheumatism; the demand for cheap shoes gives people consumption, and the demand for this sort of thing where men are not judges of the quality of work, brings about all the evils of the commercial world, and brings about many of the evils for which you call the doctor, and many of the evils which call for you to bury the poor electric wires, when it is not the electric wires at all, but it is the parent company producing unfair competition in various localities.

The secretary then read a pamphlet prepared by Mr. S. E. Barton, of the New England Insurance Exchange, relating to the subject under discussion. The pamplet showed that when properly inspected, electric lighting plants are considered by the exchange the safest of all illumination.

Prof. Houston—Those of us who have traced the progress of

Digitized by Google

electric lighting, know that during almost every decade from some time in 1810 there had been the appearance of the electric light promised, and great things blossomed for awhile and drooped. But at this time we may say that electric lighting has come to stay. It has come to stay because to-day it stands without any rival as a general artificial illuminant. It is better because it is more like sunlight; it gives a more general illumination; it is less fatiguing to the eye; it is better from a hygienic standpoint; it does not poison the air of the rooms, and I take also the stand that it is better because it is more reliable and safer than any known illuminant. It is safer to both life and property. When we contrast the electric light with the old torch; when we contrast it with the tallow candle, the coal oil lamp and the gas jet which have successively replaced one another, I think that we can all agree that, contrasted with them, it stands number one, head and shoulders above any one of them on the score of safety to both life and property. Our insurance friends will correct me if I am wrong when I say that the friction match which the electric light entirely replaces, or the uncovered gas jet, or the explosive and easily overturned coal oil lamp have been a greater destruction to both life and property during the last year than the electric light; and yet the electric light is a child of comparatively few years of age, and other systems of artificial illuminations, have been in use for a long time. Of course we must recognize that the electric light possesses dangers; that it will kill if one is stupid enough to permit the current to pass through his body. It will also ignite combustible materials if it is improperly placed. But I assert, and I think you will all agree with me, that there is no necessity in properly constructed systems of electric lighting, of either the people taking the current through their bodies or of combustible materials coming within reach of the electric currents. I know from practical experience that electric lighting can be made safe. This was tested and exemplified at the International electrical exhibition. We did not adopt the rigid rules adopted in England, and yet in a frame building we had innumerable circuits containing three thousand volts of electromotive force, and thronged with visitors, and neither was the building burned nor was there any loss of life. So we can testify that the electric light is safe. I think we should insist upon the fullest degree of inspection that our insurance friends can ask, as it is our only safety. We are not running a system that we need fear the most careful inspection of, if we only could agree among ourselves to put in the very best work, use only the very best materials, adopt freely all the well-known and well-tried danger preventives, either from fire or from loss of life, and then I do not think we need fear what the future may have in store for us. I do not think by any means that the dangers will be all removed when the electric wires are all put underground. On the contrary, as the result of very careful thought, I am confident that the time will come when from expansion or leakage, oxidation or an earthquake, or when the sewer gas escapes, and this will always take place more or less, and you cannot keep it out, then it will inevitably some day bring about contacts, and then they will be contacts of the most glorious character! Contacts that may at a moment reach different and widely separated parts of the city and place them in danger. I do not think that the problem is going to be solved as easily as many of our friends seem to think. Out of sight, out of mind. Therefore, I cannot agree with the conclusions when it is urged or hoped that the time will come when all the wires will be underground. I suppose the time will came, and must come necessarily, when all the electric wires will go underground, but I do not think anything has been shown of a scientific character which proves that the system has been perfected whereby we can safely go underground. It seems to me that it cannot be successfully done with a conduit, but you must have a subway. When you have that, the question of the underground wires will be settled. I only wish to say one thing else. It has often been remarked by people coming from England and other countries, that America had made great progress in lighting, more, probably, than any other country in the world, and it is for the very simple reason that, thus far, the electric lighting companies have been let alone and have not had their hands tied, and restrictions have not been thrown around them. But if the laws which prevail in England in reference to the matter are enforced here, then the progress of arc lighting in this country will be barred. I cannot agree with the statement as to its being unquestionably true that converters are necessarily dangerous; or that high tension electric light circuits are necessarily dangerous. They are more dangerous than others unquestionably; the question is whether they can be so regulated, whether such safeguards can be thrown around them as will render it advisable for us to use them. I think such safeguards can be. Now, only one other point; if a law should be attempted to be passed in this country limiting the electromotive force to two or three hundred volts, on the score that a higher electromotive force than that would be dangerous to life, I think we all ought to be ready to answer that question, which seems to be a very difficult one for people who wish to introduce such restrictions to answer. And that is, I doubt very much whether a person taking the electric light current is killed as a result of the current normally generated by the machine passing through his body, but that which kills him is most probably the spark produced on breaking the current contact. Again and again we read of people who turn pale, shiver and all that, and then at the moment the wire is broken falldown as dead. Why? Because if a machine capable of giving only a few hundred volts has the circuit suddenly broken, there is produced a current of several thousand volts. If that be true you do not gain any advantage when you limit the electromotive force to 200 volts. You do not make it perfectly safe, but of course it is safer than otherwise.

Dr. Moses drew attention to the fact that provision ought to be made by which a 32 c. p. lamp could not possibly be put in a 16 c. p. lamp socket, as the increased current would heat the wires dangerously. The remedy would be to put a safety catch in each lamp socket.

The president then announced the subject for the next day's meeting, and the convention adjourned for the day.

During the session a letter of invitation was read from Dr. W. H. Wahl, secretary of the Franklin Institute, asking the members of the association to attend its regular monthly meeting on the following evening, and on motion of Dr. Moses, the invitation was accepted.

Mr. De Camp also invited the members to visit the Brush Electric Light station of Philadelphia.

WEDNESDAY MORNING SESSION.

After the convention had been called to order, the secretary read a communication from the Electric Club, of New York, stating that the following resolution had been adopted by the club.

Resolved, That the president of this club appoint a committee of five, including the president, to confer with the committee that may be appointed by the National Electric Light Association, to consider the question of uniform rules and regulations to govern the installation of electric light plants; that these committees be requested to confer with the representative underwriters, and that they be solicited to take measures authorizing the appointment of a committee for the consideration of this matter with the committees above named, and that a report will be expected from this committee at the next regular meeting of the club, March 3.

The following committee had been appointed by the club: Mr. Geo. W. Hebard, president of the United States Electric Lighting Company; Mr. Geo. W. Stockly, president of the Brush company; Mr. T. A. Edison, of the Edison company; Mr. N. T. Pulsifer, of the Mather Electric company, and the president of the Electric Club, Mr. H. C. Davis, of the Sawyer-Man company.

The communication was referred to the committee named in Tuesday's report—Professor Houston, president.

Mr. Steuart, chairman of the legal committee, submitted a report on "Reforms in the Patent System." (See page 89).

Mr. Steuart read a telegram from the Hon. M. V. Montgomery, commissioner of patents, expressing that official's regret at being unable to be present.

A letter was read from the Edgerton Motor company, inviting the members of the convention to visit the establishment of the company.

Mr. J. H. Shay then read a paper on the "Transmission of Power by Belting."

Mr. Shay strongly advocated leather belting, and said: The verdict of the mechanical engineer everywhere when called to sit in judgment on this question is the same, "there is nothing like leather."

Yet there are as many kinds and forms of leather as there are of nearly any other animal product, and while for some purposes we know other leathers are better suited, the fact is undeniable that for strength, durability, ease of repair, and adhesion, oak-tanned leather stands superior to any others on all occasions. The first essential is found in the character of the hide; due care must be exercised in the tannage, and a thorough and careful selection of hides must be made to insure evenness of stock. Without particular pains in this last requisite, uniformity in the belt is impossible. Or the stock must be reduced to a uniform thickness by splitting, which introduces another fault, weakness, and consequent want of durability. Having now arrived at the point when the properly selected, tanned and sorted stock is ready for cutting and splicing, we have to decide which of several methods is best for attaching the various lengths to form a continuous belt. There are, as I have intimated, several methods of attaching these: by thongs of lace leather; by wire hooks; by rivets and burrs, and finally by scarfing and lapping—the two scarfed surfaces being cemented under pressure. This has been adopted quite generally by western manufacturers, and any objection to such joints which may have formerly existed are now set at rest forever through the use of more recent methods and materials. There are objections to the three methods first mentioned which are at once simple and damaging, from a mechanical point of view. It goes without saying that a belt punched full of holes for either lacing, hooks, rivets, or any other appliances for fastening is weakest at those splices, instead of being strongest. And again, any inequality,

Digitized by Google

such as must necessarily arise from any one of these fastenings, must result in undue strain on the belt, must give rise to a slapping motion, and thereby reduce the useful work of the power. We may find a still more serious objection further along.

Belting for electric light machinery, to be a success, must have characteristics not necessarily found in belting for other purposes. For ordinary machinery for sawing, turning, planing, etc., there is not the positive necessity for steady motion which must exist in an electric light belt to secure satisfactory results. Perfectly uniform motion, other things being equal, means steady, even, electrical force; and this, as I understand it, means uniform, steady light. Uniformity of belt must exist throughout its entire length, not only at the portion between laps, but in the laps themselves. The presence of anything which will increase the weight or thickness of the belt at the lap is no worse than at any other point, nor any less mischievous. No engineer would consider it an advantage to have the driving pulley out of true a quarter of an inch on one side, and yet this would have probably no worse effect upon the uniformity of the dynamo movement than an additional thickness at the laps of the belt.

Another cause of irregular motion may be found in a slipping belt. A certain amount of suction (of the power known among engineers as vacuum pressure), which, of course, means atmospheric pressure, is a positive necessity to hold the belt in place, and so make it pull uniformly. The more closely the belt hugs the driving pulley, of course, the more perfectly and quietly does it accomplish the end sought. Now, it takes but little thought to comprehend that a belt which is lifted from the pulley every four or five feet, allowing the air to enter the space between the belt and pulley, can only produce unsatisfactory results. Experience has demonstrated that the most perfect remedy for all this irregular action, from any of the causes mentioned, is in such a union of the laps as is produced by a scarfed joint, simply relying upon the cement, discarding rivets, pegs, wire, or any other form of fastening. To accomplish these results, there is still one vital qualification necessary which I have not mentioned. Unless the belt has been properly stretched in the manufacture, the hard, rapid pull of the dynamo work will soon render it necessary to take out the slack. This should not be.

Of the care of belting in use, a few words may not be out of place. The saturating of belting by any kind of oil is destructive. Belting stock, properly prepared, needs occasionally simply a slight coating on the grain. The dressings ordinarily offered in the market for this purpose are destructive. They are mostly of the mineral oil variety and contain more or less of those light products of distillation known as naphtha, benzine, etc., and combine readily with many vegetable and animal products, and tend to destroy their integrity.

Mr. Garratt offered the following resolution:

Resolved, That the committee on insulation be instructed not to confine their labors to the question of insulated covering for wires, but to treat the question broadly, and that at the next semi-annual convention they embody in their report a thorough treatment of the problems involved in the setting of dynamos, converters, etc., and such allied information as may seem to them appropriate. Adopted.

The president thought it would be well to change the title of that committee, and that it ought to be the proper insulation of wire and the proper installation and construction of plants.

It was agreed that that would be the title of the committee.

A resolution was adopted that a committee of three be appointed to revise and amend the by-laws, and report the same at the next meeting of the committee in August.

The secretary then read a paper by Mr. Wm. Baxter, Jr., on "Electric Motors." (See page 99.)

DISCUSSION.

Prof. Edgerton—In the paper we have just heard read, there is a suggestion which it seems to me should occupy the attention of the convention, and that is, in regard to the cost of supplying the electric current for motor purposes. What is wanted is to know whether there is going to be a large demand. If there is going to be a demand, and if it is to be permanent, I do not think there is one of you but will at once prepare for the work. Now, judging from the correspondence we have, and if we look over the field, I do not believe any man can shut his eyes to the fact that where one customer will use electric light, ten men—yes, a hundred men—will use electric power. I want to suggest that this convention appoint a committee to take in hand the matter of the price of furnishing current by the electric light people, and to prepare a list or scale of prices that would be mutually satisfactory, the committee to offer it at our next meeting.

Mr. DeCamp thought the suggestion a good one, and stated that the price they were getting for motor service in Philadelphia was 65 per cent. of that for electric light. They had no definite data to go on, but were charging at the rate of $5 per month for small sewing machine motors.

Mr. Duncan said he had had some little experience in the distribution of power with motors. They were running in Pittsburg altogether sixteen motors varying in size from a half to ten horse-power. These motors were all running with one exception upon the incandescent current. The question as to the relative cost of light service and power service was not sufficiently advanced for definite and equitable settlement. He had no hesitation in stating for the information of the association that he could obtain from the distribution of power twice as much as he could for light. They had no difficulty in placing these motors at all. The demand came to them, they did not go after it. Furthermore, the satisfaction obtained was such that they had on record in their office statements to this effect; parties who have used these motors for six months, as against steam or gas power, would be willing to pay 25 per cent. more for the electric service. Of course, that was gratuitous on their part, for he should certainly ask them next year to step up instead of down.

As regarded the maintenance of motors and the amount of service required to keep them in order he would say that as far as he could see, and as compared with an arc system, the motor requires no particular attention at all. An arc light did require particular attention, and from his experience he would say that the carbon trimmer, after a little training of a week with a motor in the shop, could, if he were at all a competent man, make a round to all the motors in service and keep them running. In Pittsburg they simply made a round twice a week to every motor in service. The man made a report. It formed part of his duties, the same as his carbon setting and the report on his lamps. He could not see why, where a light station was properly equipped for doing business, there should be any increase of force or attendance necessary, whatever, for the distribution of power, say up to 100 motors in service. That was, where the district was already covered by the light wires. I think we have arrived at that point where we can safely say that in large cities the distribution of power by means of electricity is one that will pay to run either as a separate plant or in connection with the lighting business. It is simply a question whether the lighting people are going to keep that business to themselves or whether they are going to allow somebody else to step in and take it as a separate business. In regard to the amount of investment and the relative cost, I would simply say that after we had placed four or five motors we arrived at the conclusion that it would be a very good thing for the customer to buy the motor—in other words, it would be a very good thing to have the customer interested in the business. I may say that so far the majority of our motors are owned by the subscribers, and that one person in the employ of each concern gives an eye to the motor. We make the inspection, and see that they do not crowd on more work than we guarantee when we make the bargain.

President Morrison pointed out the impossibility of having steam power so arranged as to be distributed in localities in large cities where rents are low, and where the small manufacturers, which it is the policy of municipal legislation to encourage, could be established, if the power to operate them could be obtained. Electric motors provide the means of supplying this want. He continued: I do not think that any of us have gone sufficiently into this question to be able to say whether the motor business is or is not desirable simply as an adjunct to electric lighting. I do not believe that that question can be solved except by practical work. The nearest thing to practical work that you have heard so far is the report of Mr. Duncan, of Pittsburg. He tells you that the result has been a profit to his company, and he stands a living witness to the profitableness of the motor business. With the present outlook, I believe the report of the investigators in that field to be in favor of the adoption of motors as the proper method of distributing power.

Mr. Upton said that in Boston, the motor subject had been satisfactorily taken up and dealt with. The Edison station there had motors aggregating 300 h. p. at work. It had proved a valuable addition to the economy of that station. He believed that all central lighting stations should put in motors. The additional cost was small; in some cases running all the time it was simply the cost of the coal used, with possibly the wages of a few inspectors. In fact, the whole question had been satisfactorily settled in Boston, where they were running elevators two miles from the station, both passenger and freight, with most perfect success.

Mr. Harding stated that in Boston they were getting $125 per horse-power per year for a day of 10 hours. They preferred the contract system as the only sensible one to use with the supply of intermittent power. Another point he would insist on strongly was, to sell the motors and not to rent them. They had sold every motor they had put out in the city of Boston. As a result, the customer took excellent care of the motor. When the motor was placed in a shop, a good reliable man was selected to take charge of it there, fill the oil cups, start it in the morning, etc. Then they had an inspector who went round at certain intervals to see that everything was all right. Another point was, not to have the motor overloaded. In Boston with about 40 or 50 motors they were deriving an income which was paying the local Edison company on its total original capital of $100,000, eight per cent. from power alone. Every day men were coming to the motor company wanting to buy motors. The motors were now called for in very much larger sizes, at present more 10 h. p. than any others, but 15 and 20 were in demand. These motors

Digitized by Google

had a guaranteed efficiency of 80 per cent., and the horse-power was guaranteed. They were now running the largest elevator in Boston, a freight elevator 12 feet long, 6 feet across, going 60 feet a minute. They were also running a passenger elevator going 100 feet a minute, and both were run from the same motor of about 15 h. p. A large proportion of the business was elevator work in the wholesale part of the city. About half-past 4 it was almost entirely deserted, and so the power business began to go off as the lighting came on. The circuit upon which motors were running in the day ran light also.

Mr. Morrison—That is the secret. Nearly every station is now running a day circuit which is not loaded to its full capacity.

Mr. Kerr held that only when the incandescent wires embraced the residence portion of a city would they be able to sell much beyond their actual capacity. For instance, in one town where the total call for incandescents would be 7,000 lights, the business portion took only 400 lights. Now, when they got the 7,000 lights, including the big residential area, they could rent power or light far above the station capacity. Companies that went out into residence districts found that they did not have to increase their stations so rapidly as their rented capacity would indicate. He knew stations in this way running 1,300, 1,400 and 1,500 lights from two 500 light machines, because there, if a man went to the church, theatre or hall, he didn't burn his light at home, and if all the lights were going in one house, it was because a party was going on there while all the lights in the neighboring houses were turned off, the people being at the party.

Mr. Duncan and Mr. Kerr agreed that as for instance in Pittsburg, 33 per cent. might be figured on as the excess margin that could be contracted for.

Mr. Garratt took exception to Mr. Baxter's point as to the greater cost of zinc as a fuel than coal. A good engine would not show on the pulley more than 13 per cent. of the energy in the coal burned under the boiler, so that the difference was not so great as might appear. While no man in his senses would claim that zinc was a cheaper fuel than coal to burn, there were occasions when zinc had a special use and place. He instanced a case in Boston where he furnished a motor with battery for a store. He had charged the parties a good rate for it, but they sent back, wanted to know the price for the whole, and bought it outright. Evidently there was a use for zinc as fuel.

Mr. R. T. McDonald—One thing I want to call attention to in connection with motors. We are all in the electric lighting business to make money, and the tendency in lighting has been to get prices too low. I understand it is proposed to appoint a committee to fix prices which are to be charged for motor service, and in that connection something has been said in regard to the proportion of motor rates to light rates. In some places these rates are fair, in others ruinously low. The price to be charged for motors ought to be on the basis of the cost of coal, instead of the rates charged for light.

Mr. DeCamp stated that they rented one man five motors and charged him as usual, $6 for them. They rented another man ten motors and charged him $11. The man with the ten motors gave up business or moved, and sold them to the man with five. That man threw them all in together and thus ran them a couple of months, paying $6 for the service of the fifteen. That was, perhaps, to be met by cutting out automatically when any excess was thus taken.

Mr. R. W. Pope—A similar difficulty was obviated by the Gold and Stock Telegraph Co., in New York, originally by charging the subscriber $100 for installing the quotation instrument. It was understood in the lease that this did not give him the ownership of the machine. He had the privilege of having the machine, but if he gave up business, he could not take the machine with him. The company retained the machine, also the hundred dollars. The original subscriber retained his privilege of leasing the machine. If he could find another party desirous of taking the machine, he could make a "dicker" with him. It was practical ownership, but the company thus controlled the property at all times.

It was decided to consider the motor rate proposition at the afternoon session.

WEDNESDAY AFTERNOON SESSION.

Mr. Henry Hine offered the following resolution.

Resolved, First—That the report of the legal committee be referred to a committee of five, to be called "the Committee on Patent Legislation."

Second—That it shall be the duty of this committee to carefully consider the report and proposed bill, formulate a plan for the presentation of this matter to Congress, and report at the next session of this association. Adopted.

Mr. A. F. Upton read a paper on "Plans for Installing Central Stations." He showed plans of the Boston Edison station. The *Electrical World* also presented a large 8 page folder, giving views of about a dozen stations in America and Europe, showing great difference in system of construction and equipment. Mr. Upton urged substantial equipment and economical methods of producing steam power. He said:

In starting a central station, the first matter to decide upon, is a proper location; and this requires the consideration of a number of important questions, among which are, convenience for coal and water supply, and a location central to the lighting area.

The site having been determined upon, the next question to be considered is the character of the building; brick would of course be preferable for both the boiler house and machinery building, but ordinarily the engine and dynamo rooms are constructed of wood and the boiler house of brick;—in either case allowance should be made for increase of plant in the primary structures and also sufficient land for increase of station buildings—for the inevitable necessity of this electric lighting business is to increase the plant, and the great mistake made by the pioneers of the industry has been in not allowing for this increase.

Size of buildings must be governed to a certain extent by the size of the city or town in which the station is to be located, but for an ordinary plant we find the following dimensions well adapted for the purpose; and our company has recently erected a station of these dimensions which is spoken of as a model plant.

The main building is of wood, two stories in height, with brick wall next to boiler house, and is 80 feet long by 36 feet wide; the dynamo and engine room is 16 feet in height in the clear, and the upper story (14 feet in the clear), is arranged to let power for manufacturing purposes if desired.

The boiler house is of brick, 40 feet by 40 feet, and 20 feet in height, allowing of nearly 10 feet between the boilers and roof, and in addition there is a large ventilator in the roof.

This plant starts with one tubular boiler, six feet by 16 feet, with ample room for two more of same size, and with proper passages at sides and rear of the boilers, and a 16 foot firing space in front, well paved with brick.

For a chimney they use an iron stack, 70 feet in height, 42 inches in diameter at the base and enlarging to 48 inches at the top; this stack being of size sufficient for another boiler.

They have one high speed engine, belting direct to the dynamos (one belt from each pulley of the engine), and with room for five more, which will be put in as needed.

This plant is arranged for both arc and incandescent lighting, also to furnish power for an electric railway, and when fully equipped, will easily develop 400 h. p. There is also land sufficient to duplicate this plant.

Starting on the basis that the manufacture or production of electric lights was, in reality merely selling power, we made it our aim to equip these electric lighting stations to use such apparatus and fuel as would obtain the greatest amount of steam at the least possible cost; and to avoid as far as possible, all loss between the boilers and dynamos.

The tubular boiler seems to be the standard among the electric stations, though many of the sectional boilers, especially the modern ones, have advantages well worthy of consideration. On the basis of tubular boilers, we say without reserve, to put in steel every time—don't be satisfied with homogeneous steel which can cover anything known as steel—but have specifications on flange, or better still, on fire-box steel of some good brand; for the heads, use flange steel. Don't put in a small boiler; a good six foot tubular costs but little more, takes up but a little more room, and the setting is but slightly more expensive than a five foot, while the capacity is almost double. In putting in the foundations of the boiler-setting, put them in for two boilers; they will be needed later, and such work is inconvenient when running a station.

In setting the first boiler, build one outside wall as the middle wall for a second boiler; it is also wisdom to put in an iron stack (if iron is used) large enough for two boilers, and the first cost of a pump heater, and injector large enough for two boilers is but little more than for one.

For feeding the boilers we advise using both a pump and injector, using the pump in connection with a heater when the engine is running, and having the injector as a reserve feed, also to use to furnish the boiler with hot water in case the engine is not running.

The subject of combustion of fuel is of sufficient importance among the electric light people to merit a few general remarks on the matter, and it is a subject that is far less understood by steam users than any one would suppose, considering the cost of the fuel consumed in making the steam in this country, and the following facts should interest all parties using steam power.

1st. That coal is distilled into gas before it can be properly burned.

2d. That to burn this gas, a sufficient supply of hot air must be introduced at a temperature not low enough to cool the gases below their igniting point.

3d. Every time a lot of fresh coal is thrown on the fire a great production of gas occurs, and if it is to burn to a flame it must have a corresponding supply of hot air. After a time, when the mass of fuel has become red hot, the supply of gas is greatly diminished, but at first the evolution of gas actually checks the draught;—but bear in mind that, although no smoke may be visible from the fire, it by no means follows that its combustion is perfect; if you diminish the supply of hot air, or reduce the air

Digitized by Google

space of your grate bars, you will be merely distilling carbonic oxide gas up the chimney.

4th. In ordinary boiler furnaces there is an insufficient supply of air; fresh coal is put on the grates and the firing doors are closed—gas is being distilled from this coal. Now, if you do not furnish air above the fire (and it must be hot enough to ignite the gas), how can you expect to get combustion? Whether it is expected or not it does not properly burn, and your boiler furnace is nothing more than as a gas retort in a gas works—making crude gas and wasting it up the chimney; in other words, a first-class soot and smoke factory.

Mr. Upton exhibited a number of blue prints showing the fitting up of the Edison Central Station at Boston, offering copies to any members desiring them.

The following resolution was next presented by Mr. De Camp.

Resolved, That the chair appoint a committee of five having experience in operating motors from central stations to tabulate rates for motor service, their report to be upon the basis of the price received for arc and incandescent light service, and that the report be received and considered by the next meeting of the association.

Mr. Duncan—I would suggest that it would be well to confine it to stations operating not less than 300 horse-power. I offer that as amendment.

The amendment was accepted and the resolution adopted.

The President announced as a committee on the report of the chairman of the law department, Mr. Arthur Steuart, Mr. Kerr, Mr. Ridlon, Mr. Sprague, and Mr. Morrison.

The President introduced Mr. F. J. Sprague, of New York, who addressed the convention on the subject of "Electric Motors." (See page 96.)

Mr. Sprague said, on concluding, he would be glad to answer any questions members of the convention might ask.

Dr. Moses—Will you be so kind as to tell us something about the cost of motive power?

Mr. Sprague—It is plain that in New York city the New York Steam Company is furnishing power to 435 engines. That power is supplied from a big steam station in Greenwich street. The conductors or pipes used for conveying the steam are, of course, of very large dimensions. The steam when delivered to the engine is wet steam, and the pressure is about 80, or possibly 90 pounds. There is one point of great advantage in the electrical transmission of power, in that you can work at so much higher electrical pressure than you can steam pressure. Then, again, the cost of conductors for electrical transmission is very much less than the cost of conductors for the transmission of steam, and you have not the objectionable element of wet steam. Yet here is the fact that the steam company is furnishing 435 engines with power and is making money. The consumers find it cheaper than they can generate their own steam. We found it necessary in dealing with the various light companies to have certain facts in our possession as to what we could do if we had 500 or 1,000 h. p. in a central station, as to how much power we could contract to deliver, and how much could we get for it. The manager of the Edison Central Station, in Pearl street, New York, insisted that the meter was the proper means of determining what must be paid for power. If a man uses his motor, the meter registers against him. This was done on our motors. He charged 1⅘ cents per ampere hour, and he thought he was going to have a bonanza. And so he would have had if the motors had not been automatic. After four or five months' running, we went to these people and asked them to let us see copies of their bills. We found some curious facts. I will cite one instance as showing the economy of the transmission of power by electricity:

There is a firm of chemical dealers, James L. Morgan & Co., No. 47 Fulton street, New York, who are running a freight elevator. They have a 3 h. p. motor working up to 4½ h. p. capacity. Their bills average about $12.50 per month; that is $150 per year. Had that motor been used, not up to 4½ h. p. capacity, but simply to its normal capacity of 3 h. p., steadily 10 hours a day, their bills would have been about $1,200 a year. So you see the average percentage of the time for which they use the motor is less than 15 per cent.

There you have an example of a motor, the people using it as they please, as many hours a day as they please, and they find by their meter bills that they only use that motor to 15 per cent. of its capacity. Now, we took a great many of these cases, printing offices and burnishing machines, etc., sometimes where they ran continuously and where we knew the machine was oftentimes overloaded, and we found this simple fact, viz., that with the whole capacity of motors, they average not over 33 per cent. of their capacity. In no case did we find, where they used the motor without any let up, that their bill was more than 51 per cent. of the capacity of the motor.

Mr. De Camp—Will you allow me to ask you as to the distribution of the business? Was it distributed among the class of people making up the general community?

Mr. Sprague—Yes, sir.

Mr. De Camp—How many users did it cover?

Mr. Sprague—I do not know; but it is a thing which holds, no matter how many we take. We took specimen classes of work, that is, elevators and burnishing machines, and work of that kind. All our records, however, go to show that motors, as a rule, do not average over 33 per cent. of their capacity for the 10 hours of a working day. This, in fact, is a large average. This may to a great extent be understood from the following statements: A motor is absolutely automatic. The total current used in machines of high efficiency is almost directly proportional to the work done at any instant. The result is that if the work slacks for a moment so also does the current. Almost all work is spasmodic in character. Motors have to be put in for their maximum capacity, but not one class of work out of a hundred, with the exception of ventilation, offers continuous duty. Some motors are stopped, and in others which are running the work is constantly varying from the maximum to the minimum. An illustration of this may be cited in the case of elevators. If twenty elevators, each requiring a maximum of five horse-power, were driven from the same line of counter-shafting, they would not require an engine of over forty horse-power, because some would be going up, some going down, others standing still, and in not two cases out of the twenty would simultaneous trips be made, while in not one trip in five-hundred would an elevator be hoisting its maximum load from the basement to the loft. Comparison also may be made with existing incandescent light plants. Practical experience shows that not over 55 or 60 per cent. of the total number of lights in use in a station are used at any one time, although it is possible to use them all. But incandescent lamps when they are in use take their full amount of current. Not so with motors. A certain percentage of the motors, just as with the lights, would not be in use at all, and in most of those in use the current would be continually varying, just as if the lights of an incandescent light station were being turned up and down from one to sixteen candle power, as well as many of them being turned out. The recovery in an ordinary district with 88 to 90 per cent. of the power delivered to the dynamo pulleys converted into electricity on the line and 10 per cent. loss in distribution is about 65 per cent. This 65 per cent. however, where the work is distributed, is only 33 per cent. of the capacity of the motors for which power can be contracted. In other words, for every 100 horse-power in a central station, 65 horse-power at any one instant can be delivered under an ordinary distribution, and this 65 per cent. is only one-third of the power which can be contracted for provided there are a large number of motors in use. Of course where only one motor can be used, then 65 horse-power only would be obtained, but the object of the central station is to take advantage of all the falling off of work, and that it can be done is shown by the records which we have of a large number of motors in use. The question then for central station managers is not how much can they afford to supply one, two or twenty horse-power in a single instance, assuming that to be the only power delivered; but for how much they can afford to deliver power provided, the full capacity of a certain engine is taken up by a number of motors.

The introduction of the electrical transmission of power into Boston was accomplished by the personal efforts of the president of our company, myself and our agents. The Boston company were not required to take any steps except to run their wires. We agreed to pay them $125 a horse-power per year—a pretty good price for us to make a contract for. The steam power actually costs the company about $30 to $35. Mr. Harding, then our New England agent, and now our general agent, started out to rent motors, charging $150 a year for horse-power. He pretty soon made up his mind that he would *sell* the motors. Every one put in during the past three months, has been sold. In that one station there are nearly fifty people owning motors varying from ½ to 15 horpe-power. That shows we have passed the experimental stage. We are no longer dealing with toys or theories. We are dealing with the commercial exploitation of the transmission of power. In New York city we are going to introduce motors to run the largest Hoe printing presses. We are going to prove that in dealing with these large powers we can do it more economically than it can be done by steam engines.

Mr. De Camp—Do I understand that in case I had 100 horse-power in my mill it could be furnished cheaper from an electric motor than it can be furnished by steam?

Mr. Sprague—Yes, if you are running in connection with a central station. Large engines can be operated and large powers developed under as little general supervision as smaller powers, and under far less supervision than several units of smaller powers. The cost of such generation of power is much less in larger engines, both in the amount of coal and water used and in the matter of attendance, and also in the general expense. It follows, then, that if the power of a manufacturing district can be centralized, it can be developed at a much higher efficiency and at a very much lower cost than where it is being generated in a large number of units. If, now, this power can be sent out or distributed to a large number of users in the district, then, supposing that only the same amount of power is sold as is generated in the central station, this plan of generating power would still have the advantage in point of economy. But when it is taken into

Digitized by Google

account, as has been shown, that where power is distributed to a large number of users from a central station, this station can take advantage of the very large falling off in the use of machines, it at once becomes apparent that if the system is properly constructed and operated, there is not only not a loss, but a great gain, in the centralization of steam power, and this will hold true whether dealing with a central station of 100 or 10,000 herse-power.

Mr. Ridlon—Mr. Sprague, do you think it is possible with a water power of 700 horses that is a mile away from a mill to generate 150 or 200 horse-power as cheaply as by steam?

Mr. Sprague—Yes. Of course the original investment would be more, because you would have to put in a generating station. Water power is not the most reliable thing in the world; I would rather depend upon steam. It is a question of cheap fuel. Get as much money for power with the least possible expenditure. Water power is all right provided you have plenty of it. I am going to start a central station in New York (provided the three-headed commission we have there will allow me) of 500 or 600 horse-power and working at 400 volts electromotive force, and then you will see the truth of what I tell you.

Mr. Rhodes—Is it possible to transmit water power to a distance say, of 10, 15 or 25 miles?

Mr. Sprague—Yes, sir. There is this element to consider in the transmission of power; it is just as practical a question as the transmission of energy by any other means. The moment that tne interest on your plant and the depreciation and the cost of operating exceed or equal the cost of production in the central station, just that moment do you want to drop the transmission of power.

That is, in other words, if you want to go from A to B, and that is a distance, say, of two miles, you can transmit that at a certain pressure and a given investment. If you want to go ten miles, then the question comes in, will my investment and the depreciation cost me more than if I generated my power at that point, no matter whether it is by steam or water. I know there is a great deal of talk about transmitting the power of Niagara Falls to New York city. It never will be done. The transmission of power even ten miles will not pay except in special cases, as coal is too cheap.

As an instance of the tremendous field which opens for special work, I will mention one case in which we have submitted an estimate for transmitting 200 horse-power over sixteen miles, and we have been asked to consider, also, a proposition for transmitting 600 horse-power twenty-two miles. In these cases the investment, of course, is very large. It is necessary to work with very high electromotive forces; but as to the commercial value of such transmission, you may judge from these facts: In the case where the 200 horse-power is desired to be transmitted sixteen miles they are now operating a 100 horse-power engine to supply power in three or four levels down in the mine. They do not receive over 40 to 45 horse-power. Coal of a poor quality costs about $22 a ton, and wood costs $11 a cord. It costs about $150 a day of twenty-four hours to operate this 100 horse-power engine from which only 40 horse-power is received. Sixteen miles away an ample water power is found in a river running down the side of the mountain. Here is a special case where the transmission of power, even with a very large investment, would result in a great saving.

Mr. Weissleder—How about running a street railway where the conductors are six, eight or ten miles long?

Mr. Sprague—We have to work at a potential of four, five or sometimes six hundred volts to get the highest economy in the transmission.

Dr. Moses—In running your motors at this very high electromotive force, do you feel perfectly confident as to the vitality of the machine?

Mr. Sprague—There is a limit to the electromotive force which you can use. In going to 7,000 volts I think M. Deprez has exceeded the commercial limit. All things being considered, I think 3,000 volts sufficiently high.

Mr. Ridlon—Would it be any better to use an alternating current than a constant current; the regular arc current of to-day?

Mr. Sprague—While I believe it is possible to run motors on alternating currents, I have not gone far enough into that to state what the results have been.

A number of questions were put to Mr. Sprague, which were finally summarized by Mr. Morrison as follows: It is not the intention of any of those present to discuss the motor business as a business exclusively. The question is whether they can take any part of the motor business at a profit, their business being arc lighting. Now, having a surplus of power, can that power be utilized at a profit to arc light companies? They do not propose to buy any more machinery; they do not propose to build additional lines, but to utilize the dynamos they have and to utilize the power they have.

Mr. Sprague—Unquestionably they could do that, but that limits their capacity, and it makes the motor business simply an adjunct to electric lighting. Now, that is the great fault with many Edison stations I have had to deal with, making the motor business an adjunct to the electric lighting business. If one station I have in mind had taken the capacity of their station a few weeks ago, and run it for motors, they would get double the amount they are getting for light to-day.

Mr. Powers, of Troy, N. Y., stated that he had started a separate circuit from an arc station for the purpose of supplying motors. A very large proportion of the power they would have to supply would be from 5 horse down. The difficulty they would meet is how to reconcile the first cost, if small motors be used in parallel distribution on a 600 volt constant potential circuit.

Mr. Sprague stated that with the distances in Troy 600 volts was unnecessarily high. Under suitable electromotive force the constant potential circuit would be found to be the cheaper. He said that he was considering the question of large powers and large areas, and that he was not content to deal exclusively with small powers.

Mr. Law—This motor question resolves itself into this: A majority of those here are placed in this position. We have a certain number of arc circuits up; these circuits are not full of lights. We are not allowed by the laws of the city to place any more wires on the street. Now, the question is, Is it going to pay us to put in motors or not?

Mr. Sprague—Unquestionably, yes; put all the motors you can on your circuits; the best motors you can get.

A Member—You say you are running them on incandescent circuits in New York? What effect have they on the lights, and have you any system of regulation for maintaining constant speed.

Mr. Sprague—As we are building our standard machines, they will run at the same speed, that is within one per cent., under all loads up to the maximum. The machines are absolutely automatic, Not only that, but we have machines which run on a potential varying from 180 to 220 volts; that is, on a variable constant potential circuit, if I may use the expression.

This regulation depends upon the winding entirely. A machine wound on similar principles will run at a constant speed on a constant current circuit, but only when working below 50 per cent. efficiency. If working above 50 per cent. efficiency, an automatic mechanical governor is required. It is impossible to wind a machine to run at a constant speed under variable load on a constant current circuit and work above 50 per cent. efficiency.

Mr. Duncan—We have a 60 light machine of about 2,500 volts. I am informed that we could deliver from that machine about 45 or 50 h. p.; take that as a figure. Can we run such a motor?

Mr. Sprague—You can contract to deliver that number of horse-power, if there are a large number of small motors on account of the intermittent use.

Mr. Wheeler—Why is it not as well to run out independent circuits for large powers and work on constant current circuits.

Mr. Sprague—With equal total electromotive force, the weight of wire would be the same, but with the constant current you would have a large number of circuits, the regulation would be far more difficult, and the advantage of intermittent use would be lost. There are many other objections, but these ought to be enough.

After some further discussion as to the practicability of supplying power from a constant current station,

Mr. Morrison said—Mr. Sprague takes the ground that a successful motor service should be run from a central motor station. All of Mr. Sprague's argument is that the motor business pays better than the electric light business, and I think that he has proven that very satisfactorily by the figures he has given you. But it does not entirely solve the question which is being discussed here, how arc light companies can utilize their surplus current. He told you that if he had a company that had spare power he would use it. There is another thing here, he does not care to deal with small motors. He prefers the larger sized motors, and I think he is very sensible. If you come to 1 h. p. motors and one-half h. p motors, they can be put upon the arc light circuit; if you are going to abandon the electric lighting business and go into the motor business, then take the plan that Mr. Sprague suggests.

Prof. Houston, having been introduced by the chairman, spoke as follows on

THE FUTURE OF ELECTRIC MOTORS.

I have not very much to say on the subject of motors, but it seems to me of all the bright future which seems to be in store for us as those interested in electrical matters, that in the direction of electric motors the sky appears to be the brightest. For, when we bear in mind the economy which is possible in the electric motor (and I was glad to hear Mr. Sprague speak in such unqualified terms respecting it); when we consider the very great economy of the electric motor, its small bulk and the wonderful power it is capable of rendering, it seems to me that comparatively little is needed in order to permit the steam engine to become a thing of the past, and the dynamo-electric machine become the motor of the future. Of course, as we all know, such a state of things would be impossible as long as we have to rely upon the steam engine as a prime motor to furnish the electric current; but I take it that inventive genius will not be found long wanting to devise a practical means whereby the burning of coal can be directly applied to the production of electricity; and as soon as

Digitized by Google

that is accomplished, then, beyond any question, the steam engine becomes a thing of the past—a toy—an historical piece of apparatus. And ye, fellow workers, know what that means; ye engine and boiler men know what that means—when you can pack on a small floor space a machine capable of developing three, four, five, six, seven thousand h. p. if you only have the wherewith to put into it. I think the chances are that that will be solved. I think the chances are good, and that it will be made when one succeeds in solving the problem of how to change a current of low electromotive force into one of high electromotive force.

It is recognized to-day that coal can be burned to produce electrical power, and I do not think it requires any great prophetic power, looking into the future, to see that this is not only a possibility but a probability—and of the near future. I confidently expect to live to see it.

When it was proposed to cross the Atlantic by means of steam, it was shown beyond peradventure by the very best mathematical ability, by the highest engineer authorities in the world, that it would clearly be impossible for a vessel ever to cross the Atlantic Ocean by means of steam, because, as it was argued and proved, the coal necessary to supply such a vessel would sink the ship.

Now, gentlemen, on exactly the same plan, is it not true—will you excuse me if I vaporize a little—that the only thing that stands in the way of aerial navigation to-day is compact motor power? We can certainly fly, and we can certainly navigate the air, not by means of balloons, but by some motive power, if we can get a compact motor. It seems to me not only possible, but very probable, that the electric motor may solve this particular requirement. It may not be impossible that we shall live to see flying. I certainly expect not to fly myself, as that would require considerable power, but to see machines carrying their passengers through the air.

It does seem to me that of the attractions of this field, the most practical and the one in which the future is brightest to us, is in the direction of electric motors; and I believe, too, in electric motors on arc light circuits, even electric motors in series as well as electric motors on constant potential circuits.

THURSDAY MORNING SESSION.

At the opening of the session, Mr. F. H. Ball read a paper on "Converting the Heat Energy of Coal Into Electrical Energy."

Mr. Ball's paper treated of the losses incident to the conversion of heat energy into electrical energy, and indulged in some sanguine expectations of the discovery at no distant day, of a direct conversion of the heat of coal into electricity. The paper concluded with the announcement of a new discovery in the speed regulation of engines, the nature of which was not disclosed.

The president pointed out that the loss referred to by Mr. Ball would apply not only in the case of any dynamo operated by steam, but in that of a flour mill or a cloth mill, or any other mill using steam direct. The fault lay with the engine, not with the dynamo, whose efficiency of conversion was the highest possible.

Mr. Ball admitted this, but in reply to questions from Mr. Morrison and Mr. Wetzler said he did not feel quite at liberty yet to state what was his improvement in engines relating to the governor.

The secretary read a communication from Mr. C. J. Van Depoele to Mr. G. S. Bowen, as to the success of the electric motor applied to street cars on several of the Van Depoele roads, making particular mention of those at Montgomery, Ala., Scranton, Pa., Detroit, Mich., Windsor, Ont., and Port Huron, Mich.

A paper on "Incandescent Lights on High Tension Circuits" was then read by Mr. Joseph Wetzler. (See page 90.)

At the conclusion of Mr. Wetzler's paper, it was suggested that as Dr. Moses would speak on a kindred subject it might save time to hear him next, and have the discussion on secondary batteries and secondary generators together.

Dr. Otto A. Moses, who had recently inspected the secondary generator plant at Pittsburg, put in by the Westinghouse company, then gave an extemporaneous address on "Secondary Generators." He said:

It is necessary at the outset of the address to state some of the conditions under which secondary generators can be and must be employed. The excellent paper they had just listened to pointed out one of the great difficulties in the way of the proper distribution of electric current. Mr. Sprague, yesterday, spoke of the great difficulty of running electric lights and motors from the same circuit, with present distribution. Now, to distribute current from a central station means to give what is wanted when it is wanted; but, as during the hours of night there is little demand for current, it is reasonable to suppose that at the time when energy is not being generated, the commercial value of the heavy investment in plant for producing current is not being utilized. He would suggest that that is the pivotal point upon which discussion must turn.

Dr. Moses then went on to point out that when Mr. Edison started his first large central station in New York, the principle was laid down that when a thing is wanted you must be able to supply it, and that there is no use in supplying it until it is wanted. He thought an error was made there, not in the principle, but in its application to the facts, for the true principle was to utilize your plant to the utmost by producing current without cessation. Now, as during the night there is little demand for current, the current in such a station would either have to be stored or not produced, But in order to make the plant really profitable, the current must be produced, thus utilizing the plant to the utmost extent. It followed, too, that such current should be manufactured—and stored—in places where the investment in land and realty would be brought down to a minimum. This meant for one thing carrying the agencies of current production to the place where the chief element of production was to be found. That, however, was a matter for the future. Meantime, he held that if currents of electricity are to be manufactured and handled with safety so as to take the place of other forms of energy now bought and sold, it must be delivered at low potentials where and when it is wanted in cities, but must be transmitted at high potentials from its extra mural places of low cost production. That proposition he regarded as now self-evident, and the method for such work was to be found in the use of secondary generators. The problem was to bring currents of high electromotive force from a distance and then to transform them into currents of low electromotive force. That problem had been attacked and solved.

Dr. Moses proceeded to give a brief but very interesting sketch of the development of theory and practice in the use of induction coils, dating from Faraday, and coming down to modern work with "transformers" and "secondary generators," and he called special attention to the extraordinary fact that so long a time should have passed before any one thought of reversing the action of induction coils for practical use, so as to make the fine wire coil the primary instead of the secondary. But in 1882, Gaulard, of France, undertook to make his transformer with a fine-wire primary, and thence dated the solution of the whole question as to the transmission of electrical energy from a distance.

Coming down to the introduction of the well-known Gaulard-Gibbs system in this country, Dr. Moses gave an account of his inspection of the plant as put in on the Westinghouse plan at Pittsburg. There was, he said, in that alternating current station none of the paraphernalia of enormous generators, with complicated commutators, and with all the accompanying apparatus necessary to regulate the current. They had all long ago, he believed, seen that the commutator was the weak spot in the machines for the continuous current, but in the alternating machine this commutator was done away with. In the system of secondary generation, where currents of opposite polarity are induced, there was no necessity to "correct" the currents. The currents were taken directly from the collectors as they were produced, and there was no necessity to straighten them—to change their direction—by costly and intricate commutators. These alternating machines he saw were easily manufactured. All the mechanical difficulties seemed to have been eliminated. There were simply masses of iron and massive coils, and no commutator to interfere with the proper working of the system, and the result was that these new producers of current could be made at a low cost. At Pittsburg, in fact, the whole station seemed to him to be notable for the simplicity of its details and construction. Natural gas was burned under the boilers, and the Westinghouse engine was used. In the present state of the art it was necessary to use a little exciter for the alternating machine, but he wanted to be put on record as saying that the time was not far distant when this device for exciting the fields would no longer be needed. The exciter was, however, a detail of minor importance.

Dr. Moses then gave an outline of the familiar principles involved in the use of the converters or transformers on the line, and pointed out that great flexibility of system was secured, so that any current of any potential and any quantity could be taken off where wanted. Moreover, he said, it will be possible to so change the direction of that alternating current as to effect electro deposition by it; to get off direct currents from it, and, in fact, to apply it to any use for which electricity is in demand,

After asserting his belief that with the alternating current system such great powers as Niagara could be utilized, 30,000, or even 100,000, volts potential being transformed down to large quantity currents of 5,000, 3,000, 1,000 or 500 volts, he closed by a reference to the work of Rankin Kennedy and the plan of placing the transformers in multiple arc.

DISCUSSION.

Mr. Morrison—What about the armatures of the dynamos?

Dr. Moses—The armature is one of exceeding simplicity. I saw them working right straight along, and if the thing works well once, there is no reason why it should not work well twice.

Mr. Morrison—Does it wear out?

Dr. Moses—There is nothing in it to wear out. There is metal in it, but that does not wear out, it is simply a question of making dynamos with proper insulation.

Mr. Morrison—Well, but does the insulation stand?

Dr. Moses—From the nature of the construction of the machine, I should say admirably well.

Digitized by Google

Mr. Morrison—But does it stand? How long has the apparatus been in operation?

Dr. Moses—There is a gentleman here from Pittsburg, Mr. Duncan, who is largely interested in electric lighting there—and, by the by, if you will let me say it, when I was in Pittsburg I visited his central stations, and very remarkable stations they are, like cocoons, one within the other. Mr. Duncan has investigated this subject, because, as I understand it, he has the complete control of this Westinghouse system in Allegheny county. He would, therefore, be the most proper person to speak about these questions of operation. As regards durability, beyond the mere theory of the matter, I must refer you to him.

Mr. Morrison—The only reason I have in asking these questions is that you have made specific declarations with regard to the value of this system, and that I want to find out just what you have to base that upon.

Dr. Moses—I have had correspondence on the subject, and I find that so satisfactory is the secondary generator system at present, that they are introducing in Rome a central station that will distribute to 20,000 incandescent lamps, and provision has already been made for 6,000.

Mr. Morrison said that he was after material facts and did not want to have the members blinded by the brilliant oratorical effects of the speaker. He wanted to determine the value of the thing. They had seen grow up among them a whole lot of promising electrical schemes, and they had found that when applied, many of them did not yield the results that had been expected. Now, in the case of these converters, what facts had they to go upon? How long had they been in service? What results had been obtained? Did Dr. Moses ascertain on the spot, from personal observation, the life of the apparatus and its efficiency? The life was one of the main questions. If the life was short, then there must be frequent renewal, as in the case of the storage battery.

Mr. Weissleder wished to know whether that form of current could be utilized for storage battery purposes.

Dr. Moses replied that such a plan was possible and probable. They might, he thought, do what they pleased with it—get secondary, tertiary, fourth and fifth inductions with it, the only question being as to economy with each transformation. The loss would be in each from 1½ to 2 per cent.

As to the conditions under which the apparatus worked, he could only tell them what he saw. He saw the conductor running 1½ miles from the station—making 3 miles of circuit—and they were operating on it incandescent lamps in the stores along it. They were selling those lamps in Pittsburg, the home of natural gas.

Instead of using gas, the people were buying the incandescent light. South Pittsburg, where this system was in use, he should look upon as a rather poor locality. There were not many fine stores in it. It was narrow, the worst condition, as Mr. Sprague had said, for such distribution; it was long drawn out, and not linked sweetness by any means. It went out in one direction between the river and the hill, indefinitely, and yet along that strip they distributed from their lines. It was the worst condition possible for the distribution of incandescent lights.

Mr. Morrison wanted to know whether the light was taken in that locality because it was better than gas or because it was cheaper. In Baltimore gas was 60 cents a thousand, yet his company sold lights, and at a fair price, because the light was better than gas, because the air was purer, and for all the sanitary and other reasons.

Dr. Moses said they had on the floor the representative of a firm which had been instrumental in putting in that plant, and he presumed that gentleman could give them some facts as to cost, etc. As for himself, he could say he had seen the plant working smoothly, with self-regulation, from the boilers up to the alternating current machine and the transformers. He saw but very slight movement of the voltmeter, because the current was kept so very uniform; and he saw but one man about the whole station.

Mr. W. C. Kerr, speaking for the Westinghouse system, said he was very glad to be given the opportunity to dwell on the commercial aspect of the case. He and his associates had had a great deal to do with the introduction of new things, and in fact had done nothing but develop something new. There was always a great deal of misunderstanding, a great deal of doubt, to contend with, and at the same time an undoubted desire for information. That information could not always be given in a breath. Some of Mr. Morrison's questions, for instance, were very hard for Dr. Moses to answer. Dr. Moses, as a scientist, had examined certain apparatus and had arrived at some very conclusive impressions regarding it, as they could see from his remarks; but it was not to be expected that he would be ready to answer such questions from the commercial standpoint. As to the point of durability, it could be said that the system was not fully developed, so that one could guarantee it for, say twenty years. It was simply in the condition that all new things are. Various machines have been built. The system has been put in in various places, and time must elapse in which people could form their opinions. Without intending to make any advertisement of the system, he would mention the places where the system was in operation, and where lights were being rented. There was one at the South Side, Pittsburg, which Dr. Moses mentioned, one at Greensburgh, Pa., one at Carbondale, Pa., one at Plainfield, N. J., and one at Buffalo, N. Y. A small one at Torrington would be in operation in two weeks, so that within the present spring any one near any of those places could see them in operation, and form their own conclusions. One thing he would say: In building certain new apparatus, one could observe what relation it bore to other things known to work successfully; and reasons or deductions could be formed which could not be proven in a day or a month. That was the condition the system was in at the present time. It was working. It was running successfully. The test could be made by a visit, as well as by seeing other things which it resembles or which it supersedes to a certain extent. Thus they might make the comparison between the Westinghouse three wire station on Sansom street, running about 2,300 lights, which they had visited the night before, or the station at Trenton, and then go to Plainfield and notice what the station apparatus was there, and the nature of the attendance upon the station. That was a better demonstration than anybody could stand on that floor and give. It was very difficult when a thing was new and had only been before the public three or four months, to make specific statements, by which any one would care to be bound. He thought that by the time the association visited Pittsburg they would be able to see a great deal of the system for themselves.

Mr. Morrison—That is what I wanted—to do away with the idea that this problem was absolutely solved.

Mr. C. P. Curtiss—I was in Pittsburg about a month ago, and I investigated this question then. A gentleman there who stands as high as any on this question told me that of his own positive knowledge six or seven armatures had been burned out in one machine inside of 30 days. I would like to ask Dr. Moses if he had any points in that direction.

Dr. Moses—I passed about half a day in the station. I looked everywhere that I was permitted to look. I had also, I am very glad to say, an opportunity, in the enormous factories of the Westinghouse company, to see all the details of construction. Perhaps for that reason I should be guarded in what I say, because I know that in such large establishments there may be things going on which should not be spoken of. As far as the armatures are concerned, I had the privilege of seeing them manufactured, from the first stages up to their completion. I have had some experience in making dynamo machines, and I do not see why they should there continue in certain grooves of systematic manufacture, as they seem to if those machines were burning out so rapidly. It seems to me that I would "swap horses" if my armatures burned out six a day, or a week, or a month. But they appeared to be making the armatures in a regular systematic way, just as all of Mr. Westinghouse's machines and appliances are manufactured.

Mr. De Camp said that this system appeared to be an old thing recently renovated, and there must be some suspicion as to the merit of it, or else being so long known, it would have been more generally utilized. One of the objections he had heard was on the score of safety. Then he wanted to know what was its economy, what was the loss in induction. One gentleman had said to him that if those wires were run in front of an iron building it would create induction and loss of current.

Mr. Slattery regretted that Mr. Moses had made an omission of everything that could really guide them in determining the commercial efficiency of the system. He also took exception to the statement of Dr. Moses that prior to the work of Gaulard and Gibbs, no coil had been made to transform high tension into low tension current. The very coil of Faraday that the doctor had referred to was composed of about No. 14 B. & S. gauge, and he believed that the primary and secondary wires were nearly identical in diameter and in number of turns, which after all were factors that would give them the necessary conditions in a commercial system of illumination if placed upon a multiple arc circuit or on a series circuit such as the Gaulard and Gibbs. That was to say, if they passed 10 amperes through that primary—and No. 14 B. & S. had a perfectly safe carrying capacity for 10 or 12 amperes—they would get commercial results in the secondary circuits or, in other words, they could operate incandescent lamps. Although he wanted precise information as to this particular system, Mr. Slattery said there was no doubt at all about the fact, as a fact, that the transformation from high tension into low tension could be done efficiently.

Mr. Duncan, after taking occasion to protect the good fame and character of natural gas as used in Pittsburg, went on to speak of the work he was doing in supplying incandescent lights there, and of the reasons why that light was preferred there, as against cheap gas of any kind. Hitherto he said, that they always had a very dirty city, except during the last two years, when they had brightened up a little. It had been a city of gloom, heavy fogs, etc., but the gas had been very poor. Latterly, owing to the competition, however, the gas companies had been stirred up, with the consequence that they got a very excellent quality of illuminating

Digitized by Google

gas now at from 80 cents to $1 per 1,000. But the people preferred the incandescent light. It was easily handled. It was a cleaner article than gas.

The Pittsburg Light company, organized and operating on the south side, was using the system with machinery, which had been in operation there for two weeks. It was pretty hard to say after two weeks, as to the economy of the system, or as to why one armature burned out, or a dozen. It was not so long ago, as they knew, that arc light machines burned out. That question, anyhow, it seemed to him, ought to be left out. It was not a fair matter of discussion before the convention. But there was the Greensburgh plant. He had been told by Greensburg people that some armatures burned out, but he had also been told by the engineer in charge of that station that an armature in one of the machines had been running for four weeks consecutively; and he claimed that an armature running four weeks would run indefinitely. It was a problem of mechanical construction, and he did not think it entered into that discussion at all, and he did not see how any question of burning of armatures could militate against the proper consideration of the system. As for himself, when he first looked into the system, he did not think very favorably of it, but after several visits to Greensburg, and after seeing the operation in the South Side station, where everything was running smoothly with 600 lights and the regulation in the station was as close as 2½ to 3 per cent., he had begun to think that there was a very great future for it, and he could not see why there should not be. He invited the members to correspond with him on the subject, promising to give them any information he could. All he could state now was that the system had not been sufficiently developed for any man to speak as to the relative merits, in dollars and cents.

Mr. Powers pointed out that under any conditions, to carry a current any great distance, whether it be alternating or direct, there must be a percentage of loss, and practically the loss in each case must be precisely the same for the conveyance of the current. With the alternating current they gained flexibility of system and paid for that the cost of conversion. As to the question of danger, he had had some experience with alternating current machine manufacture, and knew something about the effects of the alternating current upon the human system. Those effects were extremely unpleasant. He would rather take a sharp shock from a direct current of 1,000 volts than from an alternating current of 500 volts. Mr. Powers also suggested that there would be danger of accident if any one in a building were to stand on a radiator or something of that kind and as one might unthinkingly take hold of the secondary connection of the lamp or lamp holder. Would there not be extreme danger of a current of that potential destroying the insulation? Would it not be likely to produce fatal results there? That struck him as the most dangerous aspect of the case, as fires might be produced in that way.

Mr. Kimball—I should take pleasure in answering the two questions, and I would like to read two or three notes that may have a direct bearing on this question of distribution by alternating currents.

In 1877, Prof. Thomson, now of the Thomson-Houston Electric Co., of Boston, delivered a lecture and, among other things, proved to his audience the reversibility of the induction coil and also that the discharge of static electricity was identically the same as that of a continuous current from batteries. One of his experiments was the passing of a current from several gallon Leyden jars through the fine wire of an induction coil or its secondary circuit, as it is more commonly designated; the *ends* of the coarse wire or *primary* coil, having been previously brought into slight contact, a bright spark and a fusion of the wire ends resulted, sufficient to cause the terminals to stick together; thus at that early day giving a forecast of the method of electric welding, which has since been developed into a practicable electro-mechanical process. Experiments were carried on by Professors Thomson and Houston during 1878 and 1879; coils of insulated copper were made of a hoop shape and wound over with an iron wire sheathing.

This, of course, was before the incandescent lamp had been brought to a suitable condition for commercial use. Since the production of the incandescent lamp, these researches have been extended with a view to developing a complete system to meet the requirements of long-distance transmission of electrical energy. How successfully must be demonstrated by the apparatus itself. I may, however, briefly mention a dynamo machine which is self exciting and automatic in its regulation for any number of lamps turned off or on up to the capacity of the machine, delivering a current alternating in its direction through the line, and, upon such a circuit—in which the usual form of electro-magnet reacts upon itself to such an extent that its temperature may be raised to the melting point—apparatus has been devised having all the properties of electro-magnets, giving a push or a pull proportionate to the current expended, thus enabling the construction of direct reading voltmeters and ammeters, arc lamps, the running of specially constructed motors for the distribution of power, and still further, the operation of plating machines and of electrical devices for measuring the alternating impulses given to the line, all being supplied from the same wire. Safety devices are used which make the danger to life and property no greater in the building or residence than with the low tension dynamo of 100 volts difference of potential with which we are familiar. Still more, it has been demonstrated that although the wiring of this system follows the laws of multiple arc conductors, and points widely separated are subject to a rise or fall in their E. M. F., that a means is at hand for equalizing these discrepancies in such a manner as to maintain the entire network in constant equilibrium at an even difference of potential at the poles of the lamp under great changes in the number of lamps connected, and while not *necessarily* depreciating other apparatus, we have opened up an immense field of incandescent electric lighting at a distance from the central station.

Mr. Carl Hering rose to correct an impression that had been formed as to the apparatus shown at the Franklin Institute by him on the previous evening, and about which he had remarked that the coil used would disintegrate quickly. It was the Zipernowski-Deri, whereas the Westinghouse coil, as they all know, was the Gaulard-Gibbs. He also called attention briefly to the work of Mr. Gordon in England.

Mr. Weissleder moved that a committee be appointed to report on secondary distribution at the next meeting of the convention.

Mr. De Camp asked as to potential used in Pittsburg.

Mr. Duncan—About 1,000 volts.

Mr. De Camp—Are the converters put inside or outside the building?

Mr. Duncan—They are in most cases placed upon the poles between the two cross-arms; and in another case, where there is a distribution of 250 or 300 lights, I understand that they have put the boxes inside the building in the cellar.

Mr. De Camp—They put them on the poles because it is objectionable to put them inside?

Mr. Duncan—As I understand it, it is a matter of convenience for distribution, for the reason that if you take the ordinary store such as we have to deal with on the South Side, they only require on the average fifteen 16 c. p. lights; and as the poles are, I presume, about 140 to 160 feet apart, it is a matter of economy to place those converter boxes upon the poles and thence to distribute to either side of the streets, running off lines accordingly. The place where there is a distributor in the house is in a public building, of about 250 lights. They put a converter in that case in the second story of the Market House as a matter of convenience for distribution.

The following committee on secondary distribution was then appointed:—Messrs. Weissleder, Slattery and Carl Hering.

An interval in the discussion on secondary generators was occupied by Mr. C. J. Kintner, examiner of the U. S. patent office in Class Electricity. Mr. Kintner dealt briefly with the subject of Patent Office Reform.

He wished to make some extenuation of what Mr. Steuart had reported, while heartily commending the report and the efforts that gentleman outside the patent office were making in the direction of reform. He wanted them, however, to appreciate the difficulties of the position in which he was placed as a public officer in carrying out in anything like a successful manner the business of properly examining the applications which came before the patent office. He professed to be perhaps as well prepared, theoretically, as most of them, to cope with the technical questions arising, but he was without the apparatus that any well organized institution like the patent office ought to have. To-day they had in that office a laboratory the total material of which cost less than $500! A little over a year ago it became his privilege as chief of the electrical division to recommend to the commissioner of patents a system which, in his opinion, would put the experts of the patent office upon a par with those outside in every respect. He recommended in his report that a central plant be stationed within the court of the building, that a workshop should be organized, and that a system of heating and lighting the building be combined there, by which it would be possible to light and to heat without any other expense, and the apparatus would pay for itself. No progress had yet been made in that direction, however, and, in fact, if they would look back through the reports of the commissioner of patents they would find the same old story regularly repeated of want of room, want of force, want of everything which would go to make a complete system of examination of patents. Yet they did their work in a creditable manner, turning out patents of which he ventured to say that four-fifths would be sustained by the courts. It was marvelous how they did it.

M. Kintner then called attention to the fact that the rapid development of electricity had necessitated the division of his department into two sections, and urged that the whole matter of reform and attention to wants, as suggested in Mr. Steuart's report, lay in the hands of the members themselves, as inventors or users of patented apparatus. He also considered the suggestion as to the patent court as eminently proper. The present system of appeals, too, was, to use a vulgar but pithy expression, "tail-end-too." The examiner in charge of a division is an expert upon the merits of a case, and he is appealed from to

Mr. Morrison—But does it stand? How long has the apparatus been in operation?

Dr. Moses—There is a gentleman here from Pittsburg, Mr. Duncan, who is largely interested in electric lighting there—and, by the by, if you will let me say it, when I was in Pittsburg I visited his central stations, and very remarkable stations they are, like cocoons, one within the other. Mr. Duncan has investigated this subject, because, as I understand it, he has the complete control of this Westinghouse system in Allegheny county. He would, therefore, be the most proper person to speak about these questions of operation. As regards durability, beyond the mere theory of the matter, I must refer you to him.

Mr. Morrison—The only reason I have in asking these questions is that you have made specific declarations with regard to the value of this system, and that I want to find out just what you have to base that upon.

Dr. Moses—I have had correspondence on the subject, and I find that so satisfactory is the secondary generator system at present, that they are introducing in Rome a central station that will distribute to 20,000 incandescent lamps, and provision has already been made for 6,000.

Mr. Morrison said that he was after material facts and did not want to have the members blinded by the brilliant oratorical effects of the speaker. He wanted to determine the value of the thing. They had seen grow up among them a whole lot of promising electrical schemes, and they had found that when applied, many of them did not yield the results that had been expected. Now, in the case of these converters, what facts had they to go upon? How long had they been in service? What results had been obtained? Did Dr. Moses ascertain on the spot, from personal observation, the life of the apparatus and its efficiency? The life was one of the main questions. If the life was short, then there must be frequent renewal, as in the case of the storage battery.

Mr. Weissleder wished to know whether that form of current could be utilized for storage battery purposes.

Dr. Moses replied that such a plan was possible and probable. They might, he thought, do what they pleased with it—get secondary, tertiary, fourth and fifth inductions with it, the only question being as to economy with each transformation. The loss would be in each from 1½ to 2 per cent.

As to the conditions under which the apparatus worked, he could only tell them what he saw. He saw the conductor running 1½ miles from the station—making 3 miles of circuit—and they were operating on it incandescent lamps in the stores along it. They were selling those lamps in Pittsburg, the home of natural gas.

Instead of using gas, the people were buying the incandescent light. South Pittsburg, where this system was in use, he should look upon as a rather poor locality. There were not many fine stores in it. It was narrow, the worst condition, as Mr. Sprague had said, for such distribution; it was long drawn out, and not linked sweetness by any means. It went out in one direction between the river and the hill, indefinitely, and yet along that strip they distributed from their lines. It was the worst condition possible for the distribution of incandescent lights.

Mr. Morrison wanted to know whether the light was taken in that locality because it was better than gas or because it was cheaper. In Baltimore gas was 60 cents a thousand, yet his company sold lights, and at a fair price, because the light was better than gas, because the air was purer, and for all the sanitary and other reasons.

Dr. Moses said they had on the floor the representative of a firm which had been instrumental in putting in that plant, and he presumed that gentleman could give them some facts as to cost, etc. As for himself, he could say he had seen the plant working smoothly, with self-regulation, from the boilers up to the alternating current machine and the transformers. He saw but very slight movement of the voltmeter, because the current was kept so very uniform; and he saw but one man about the whole station.

Mr. W. C. Kerr, speaking for the Westinghouse system, said he was very glad to be given the opportunity to dwell on the commercial aspect of the case. He and his associates had had a great deal to do with the introduction of new things, and in fact had done nothing but develop something new. There was always a great deal of misunderstanding, a great deal of doubt, to contend with, and at the same time an undoubted desire for information. That information could not always be given in a breath. Some of Mr. Morrison's questions, for instance, were very hard for Dr. Moses to answer. Dr. Moses, as a scientist, had examined certain apparatus and had arrived at some very conclusive impressions regarding it, as they could see from his remarks; but it was not to be expected that he would be ready to answer such questions from the commercial standpoint. As to the point of durability, it could be said that the system was not fully developed, so that one could guarantee it for, say twenty years. It was simply in the condition that all new things are. Various machines have been built. The system has been put in in various places, and time must elapse in which people could form their opinions. Without intending to make any advertisement of the system, he would mention the places where the system was in operation, and where lights were being rented. There was one at the South Side, Pittsburg, which Dr. Moses mentioned, one at Greensburgh, Pa., one at Carbondale, Pa., one at Plainfield, N. J., and one at Buffalo, N. Y. A small one at Torrington would be in operation in two weeks, so that within the present spring any one near any of those places could see them in operation, and form their own conclusions. One thing he would say: In building certain new apparatus, one could observe what relation it bore to other things known to work successfully; and reasons or deductions could be formed which could not be proven in a day or a month. That was the condition the system was in at the present time. It was working. It was running successfully. The test could be made by a visit, as well as by seeing other things which it resembles or which it supersedes to a certain extent. Thus they might make the comparison between the Westinghouse three wire station on Sansom street, running about 2,300 lights, which they had visited the night before, or the station at Trenton, and then go to Plainfield and notice what the station apparatus was there, and the nature of the attendance upon the station. That was a better demonstration than anybody could stand on that floor and give. It was very difficult when a thing was new and had only been before the public three or four months, to make specific statements, by which any one would care to be bound. He thought that by the time the association visited Pittsburg they would be able to see a great deal of the system for themselves.

Mr. Morrison—That is what I wanted—to do away with the idea that this problem was absolutely solved.

Mr. C. P. Curtiss—I was in Pittsburg about a month ago, and I investigated this question then. A gentleman there who stands as high as any on this question told me that of his own positive knowledge six or seven armatures had been burned out in one machine inside of 30 days. I would like to ask Dr. Moses if he had any points in that direction.

Dr. Moses—I passed about half a day in the station. I looked everywhere that I was permitted to look. I had also, I am very glad to say, an opportunity, in the enormous factories of the Westinghouse company, to see all the details of construction. Perhaps for that reason I should be guarded in what I say, because I know that in such large establishments there may be things going on which should not be spoken of. As far as the armatures are concerned, I had the privilege of seeing them manufactured, from the first stages up to their completion. I have had some experience in making dynamo machines, and I do not see why they should there continue in certain grooves of systematic manufacture, as they seem to if those machines were burning out so rapidly. It seems to me that I would "swap horses" if my armatures burned out six a day, or a week, or a month. But they appeared to be making the armatures in a regular systematic way, just as all of Mr. Westinghouse's machines and appliances are manufactured.

Mr. De Camp said that this system appeared to be an old thing recently renovated, and there must be some suspicion as to the merit of it, or else being so long known, it would have been more generally utilized. One of the objections he had heard was on the score of safety. Then he wanted to know what was its economy, what was the loss in induction. One gentleman had said to him that if those wires were run in front of an iron building it would create induction and loss of current.

Mr. Slattery regretted that Mr. Moses had made an omission of everything that could really guide them in determining the commercial efficiency of the system. He also took exception to the statement of Dr. Moses that prior to the work of Gaulard and Gibbs, no coil had been made to transform high tension into low tension current. The very coil of Faraday that the doctor had referred to was composed of about No. 14 B. & S. gauge, and he believed that the primary and secondary wires were nearly identical in diameter and in number of turns, which after all were factors that would give them the necessary conditions in a commercial system of illumination if placed upon a multiple arc circuit or on a series circuit such as the Gaulard and Gibbs. That was to say, if they passed 10 amperes through that primary—and No. 14 B. & S. had a perfectly safe carrying capacity for 10 or 12 amperes—they would get commercial results in the secondary circuits or, in other words, they could operate incandescent lamps. Although he wanted precise information as to this particular system, Mr. Slattery said there was no doubt at all about the fact, as a fact, that the transformation from high tension into low tension could be done efficiently.

Mr. Duncan, after taking occasion to protect the good fame and character of natural gas as used in Pittsburg, went on to speak of the work he was doing in supplying incandescent lights there, and of the reasons why that light was preferred there, as against cheap gas of any kind. Hitherto he said, that they always had a very dirty city, except during the last two years, when they had brightened up a little. gas now at from 80 cents to $1 per 1,000. But the people preferred the incandescent light. It was easily handled. It was a cleaner article than gas.

The Pittsburg Light company, organized and operating on the south side, was using the system with machinery, which had been in operation there for two weeks. It was pretty hard to say after two weeks, as to the economy of the system, or as to why one armature burned out, or a dozen. It was not so long ago, as they knew, that arc light machines burned out. That question, anyhow, it seemed to him, ought to be left out. It was not a fair matter of discussion before the convention. But there was the Greensburgh plant. He had been told by Greensburg people that some armatures burned out, but he had also been told by the engineer in charge of that station that an armature in one of the machines had been running for four weeks consecutively; and he claimed that an armature running four weeks would run indefinitely. It was a problem of mechanical construction, and he did not think it entered into that discussion at all, and he did not see how any question of burning of armatures could militate against the proper consideration of the system. As for himself, when he first looked into the system, he did not think very favorably of it, but after several visits to Greensburg, and after seeing the operation in the South Side station, where everything was running smoothly with 600 lights and the regulation in the station was as close as 2½ to 3 per cent., he had begun to think that there was a very great future for it, and he could not see why there should not be. He invited the members to correspond with him on the subject, promising to give them any information he could. All he could state now was that the system had not been sufficiently developed for any man to speak as to the relative merits, in dollars and cents.

Mr. Powers pointed out that under any conditions, to carry a current any great distance, whether it be alternating or direct, there must be a percentage of loss, and practically the loss in each case must be precisely the same for the conveyance of the current. With the alternating current they gained flexibility of system and paid for that the cost of conversion. As to the question of danger, he had had some experience with alternating current machine manufacture, and knew something about the effects of the alternating current upon the human system. Those effects were extremely unpleasant. He would rather take a sharp shock from a direct current of 1,000 volts than from an alternating current of 500 volts. Mr. Powers also suggested that there would be danger of accident if any one in a building were to stand on a radiator or something of that kind and as one might unthinkingly take hold of the secondary connection of the lamp or lamp holder. Would there not be extreme danger of a current of that potential destroying the insulation? Would it not be likely to produce fatal results there? That struck him as the most dangerous aspect of the case, as fires might be produced in that way.

Mr. Kimball—I should take pleasure in answering the two questions, and I would like to read two or three notes that may have a direct bearing on this question of distribution by alternating currents.

In 1877, Prof. Thomson, now of the Thomson-Houston Electric Co., of Boston, delivered a lecture and, among other things, proved to his audience the reversibility of the induction coil and also that the discharge of static electricity was identically the same as that of a continuous current from batteries. One of his experiments was the passing of a current from several gallon Leyden jars through the fine wire of an induction coil or its secondary circuit, as it is more commonly designated; the *ends* of the coarse wire or *primary* coil, having been previously brought into slight contact, a bright spark and a fusion of the wire ends resulted, sufficient to cause the terminals to stick together; thus at that early day giving a forecast of the method of electric welding, which has since been developed into a practicable electro-mechanical process. Experiments were carried on by Professors Thomson and Houston during 1878 and 1879; coils of insulated copper were made of a hoop shape and wound over with an iron wire sheathing.

This, of course, was before the incandescent lamp had been brought to a suitable condition for commercial use. Since the production of the incandescent lamp, these researches have been extended with a view to developing a complete system to meet the requirements of long-distance transmission of electrical energy. How successfully must be demonstrated by the apparatus itself. I may, however, briefly mention a dynamo machine which is self exciting and automatic in its regulation for any number of lamps turned off or on up to the capacity of the machine, delivering a current alternating in its direction through the line, and, upon such a circuit—in which the usual form of electro-magnet reacts upon itself to such an extent that its temperature may be raised to the melting point—apparatus has been devised having all the properties of electro-magnets, giving a push or a pull proportionate to the current expended, thus enabling the construction of direct reading voltmeters and ammeters, arc lamps, the running of specially constructed motors for the distribution of power, and still further, the operation of plating machines and of electrical devices for measuring the alternating impulses given to the line, all being supplied from the same wire. Safety devices are used which make the danger to life and property no greater in the building or residence than with the low tension dynamo of 100 volts difference of potential with which we are familiar. Still more, it has been demonstrated that although the wiring of this system follows the laws of multiple arc conductors, and points widely separated are subject to a rise or fall in their E. M. F., that a means is at hand for equalizing these discrepancies in such a manner as to maintain the entire network in constant equilibrium at an even difference of potential at the poles of the lamp under great changes in the number of lamps connected, and while not *necessarily* depreciating other apparatus, we have opened up an immense field of incandescent electric lighting at a distance from the central station.

Mr. Carl Hering rose to correct an impression that had been formed as to the apparatus shown at the Franklin Institute by him on the previous evening, and about which he had remarked that the coil used would disintegrate quickly. It was the Zipernowski-Deri, whereas the Westinghouse coil, as they all know, was the Gaulard-Gibbs. He also called attention briefly to the work of Mr. Gordon in England.

Mr. Weissleder moved that a committee be appointed to report on secondary distribution at the next meeting of the convention.

Mr. De Camp asked as to potential used in Pittsburg.

Mr. Duncan—About 1,000 volts.

Mr. De Camp—Are the converters put inside or outside the building?

Mr. Duncan—They are in most cases placed upon the poles between the two cross-arms; and in another case, where there is a distribution of 250 or 300 lights, I understand that they have put the boxes inside the building in the cellar.

Mr. De Camp—They put them on the poles because it is objectionable to put them inside?

Mr. Duncan—As I understand it, it is a matter of convenience for distribution, for the reason that if you take the ordinary store such as we have to deal with on the South Side, they only require on the average fifteen 16 c. p. lights; and as the poles are, I presume, about 140 to 160 feet apart, it is a matter of economy to place those converter boxes upon the poles and thence to distribute to either side of the streets, running off lines accordingly. The place where there is a distributor in the house is in a public building, of about 250 lights. They put a converter in that case in the second story of the Market House as a matter of convenience for distribution.

The following committee on secondary distribution was then appointed:—Messrs. Weissleder, Slattery and Carl Hering.

An interval in the discussion on secondary generators was occupied by Mr. C. J. Kintner, examiner of the U. S. patent office in Class Electricity. Mr. Kintner dealt briefly with the subject of Patent Office Reform.

He wished to make some extenuation of what Mr. Steuart had reported, while heartily commending the report and the efforts that gentleman outside the patent office were making in the direction of reform. He wanted them, however, to appreciate the difficulties of the position in which he was placed as a public officer in carrying out in anything like a successful manner the business of properly examining the applications which came before the patent office. He professed to be perhaps as well prepared, theoretically, as most of them, to cope with the technical questions arising, but he was without the apparatus that any well organized institution like the patent office ought to have. To-day they had in that office a laboratory the total material of which cost less than $500! A little over a year ago it became his privilege as chief of the electrical division to recommend to the commissioner of patents a system which, in his opinion, would put the experts of the patent office upon a par with those outside in every respect. He recommended in his report that a central plant be stationed within the court of the building, that a workshop should be organized, and that a system of heating and lighting the building be combined there, by which it would be possible to light and to heat without any other expense, and the apparatus would pay for itself, No progress had yet been made in that direction, however, and, in fact, if they would look back through the reports of the commissioner of patents they would find the same old story regularly repeated of want of room, want of force, want of everything which would go to make a complete system of examination of patents. Yet they did their work in a creditable manner, turning out patents of which he ventured to say that four-fifths would be sustained by the courts. It was marvelous how they did it.

M. Kintner then called attention to the fact that the rapid development of electricity had necessitated the division of his department into two sections, and urged that the whole matter of reform and attention to wants, as suggested in Mr. Steuart's report, lay in the hands of the members themselves, as inventors or users of patented apparatus. He also considered the suggestion as to the patent court as eminently proper. The present system of appeals, too, was, to use a vulgar but pithy expression, "tail-end-too." The examiner in charge of a division is an expert upon the merits of a case, and he is appealed from to

Digitized by Google

the board of examiners-in-chief, of whom, it might be said, without any disrespect, that they were not experts in that special line any more than in the other 26 arts, as represented in the divisions of the patent office. Thence appeal lies to the commissioner of patents, who necessarily an able man in the law, does not pretend to be an expert in those technical branches; and from him to the District Court of the District of Columbia, and by appeal in equity to the Supreme Court of the United States. It would, therefore, be a proper course to pursue to provide such a patent court, to sit in judgment upon all disputed cases, all matters as to the merits of the cases, and all questions of infringement, so as to get unanimity and uniformity of decisions. Mr. Kintner closed by saying that he did not speak selfishly for himself. He did not expect to remain in the office another year, and was all the time in receipt of tempting offers to leave. The fact was that the personnel was constantly changing, because of the inducements from outside. While the changes he asked for would not benefit him now, they would do good to the office, and to inventors in the future,

The president then introduced to the meeting Mr. Ichisuki Fujioka, M. E., of Tokio, Japan, who was warmly received, and read a brief paper entitled "A Short Sketch of the Progress of Electrical Engineering in Japan." (See page 101.)

Mr. Weeks then expressed the pleasure felt by the convention in listening to the address, and said: "I am confident our friends abroad in the electric lighting business are pretty well assured that we have the deepest sympathy with them, and entertain toward them the most kindly feelings."

Messrs. Fujioka and Yashima were then elected honorary members of the association.

Mr. Yashima, president of the Tokio Electric Light Co., responded to the compliment.

Mr. Weissleder, chairman of the committee on nominations, having reported, the following officers were unanimously elected: President (third term), J. F. Morrison; vice-presidents, E. R. Weeks, A. J. DeCamp; executive committee, F. A. Gilbert, chairman, G. S. Bowen, F. Ridlon, C. Holbrook, Otto A. Moses, E. T. Lynch, Jr., and J. F. Noonan; treasurer, C. Cooper.

Mr. Morrison, on resuming the chair as president, said that for any man to declare that it was not an honor to be elected to the office would be saying what was not true, and the convention would not believe it. It was an honor, and one which he fully appreciated. At the same time he did not believe that the association acted wisely in re-electing the old officers year after year. He accepted the office with the hope that the same good will and kindness that had been shown toward him in the past would still be extended.

The next question being as to the place of meeting in the summer, Mr. Upton said he had been requested by Mr. Barton, of the Thomson-Houston Co., to suggest Boston.

The same suggestion came from Mr. F. A. Gilbert, president of the Boston Electric Light Co.

Boston was then chosen as the place of the next meeting, to be held in August next.

Mr. Duncan called attention to Pittsburg as a good meeting place one year from this time.

No further business being presented, the convention then adjourned.

The convention was attended by the following members and visitors:

Attleboro, Mass.—H. M. Daggett, Jr.
Baltimore.—W. Baxter, Jr., J. Evans, T. McCoubray, Jr., C. R. Deacon, Dr. L. Duncan, B. M. Greene, W. M. McDermott, J. F. Morrison, C. Selden, C. R. Sharretts, A. Steuart, D. H. Tuxworth.
Binghamton.—J. Anderson.
Boston.—W. I. Barker, S. E. Barton, C. E. Bibber, W. F. Brewster, H. B. Cram, H. H. Eustis, A. V. Garratt, H. McL. Harding, C. W. Holtzer, A. F. Mason, F. Ridlon, R. F. Ross, L. Schlegelmilch, E. S. Sears, A. F. Upton.
Bridgeport.—H. L. Bancroft, H. D. Stanley.
Brooklyn.—E. F. Peck, W. D. Sargent.
Buffalo, N. Y.—J. C. Weber.
Camden, N. J.—F. Reed.
Cincinnati.—L. H. Weissleder, W. L. Silvey.
Cleveland.—J. B. Crouse, C. P. Curtiss, W. A. Lawrence, F. B. Pettengill, J. Potter, C. D. Smith, C. L. Wright.
Chicago.—W. J. Buckley, C. K. Giles, H. A. Glasier, F. W. Harrington, C. C. Haskins, J. H. Shay, F. Stewart.
E. Cambridge, Mass.—S. O. Richardson, Jr.
Elizabeth, N. J.—P. Diehl, J. G. Greene, H. W. Pope.
Easton, Md.—J. H. Covington, C. T. Wrightson.
Elgin, Ill.—Wm. Hubbard.
Erie, Pa.—F. H. Ball.
Fitchburg, Mass.—F. Fosdick.
Fort Wayne, Ind.—R. T. McDonald.
Harrisburg, Pa.—E. Mather.
Hartford, Conn.—W. M. Bond, J. A. Dalzell, H. M. Linnell, M. J. Wightman, C. G. Young.
Jamestown, N. Y.—D. H. Smith.
Kansas City.—E. R. Weeks.
Lacrosse, Wis.—S. R. Montague.
North Adams, Mass.—H. E. Wetherbee.
Newark.—C. O. Baker, Jr., C. McIntyre.
New Haven.—F. A. Gilbert, J. Gilbert.
New York.—P. C. Ackerman, J. L. Barclay, J. W. Beane, G. L. Beetle, A. W. Butterworth, W. M. Callender, W. L. Candee, D. Chalmers, H. C. Davis, J. O. Ellinger, J. P. Ford, E. F. Gennert, C. W. Gould, C. B. Hotchkiss, H. Hall, A. S. Hibbard, H. Hine, H. B. Hungerford, W. J. Johnston, J. F. Kelly, W. C. Kerr, F. E. Kinsman, H. L. Lufkin, E. T. Lynch, Jr., Geo. T. Manson, T. C. Martin, Dr. Otto A. Moses, G. M. Phelps, Jr., R. W. Pope, J. B. Powell, C. W. Price, H. A. Reed, R. W. Ryan, H. W. Spang, F. J. Sprague, F. G. Stone, C. E. Stump, C. R. Truex, J. S. Walters, Arthur K. Watt, S. S. Wheeler, J. Wetzler, G. L. Wiley, G. Worthington.
Niagara Falls.—B. Rhodes.
Olneyville, Mass.—R. T. Robinson.
Philadelphia.—A. Bournonville, G. W. Boyer, W. C. Bryant, H. A. Cleverly, A. J. DeCamp, T. Dolan, N. H. Edgerton, H. S. Foster, H. C. Frempt, H. A. Fuller, M. M. Garver, W. A. Giles, Carl Hering, S. Holbrooke, H. Horne, Prof. E. J. Houston, W. C. Johnson, M. D. Law, W. D. Marks, - — McDevitt, A. F. Moore, M. R. Muckle, Jr.. E. D. Mullen, H. G. Oesterle, A. Partz, James A. Pentz, H. A. Pitcher, J. W. Queen, C. A. G. Riege, S. B. Richards, P. H. Richardson, W. M. Schlesinger, P. G. Salom, J. R. Simpson, W. E. Sharpe, A. L. Snowden, C. W. Tisdall, C. E. Trump, G. A. Wilbur, Chester Wilson, D. T. Van Dyke, J. L. Welsh, E. W. Wilkins, C. M. Wilkins.
Pittsburg.—S. A. Duncan, Z. Latshaw, G. F. Porter, H. A. Rehan.
Portland, Me.—F. A. Sawyer.
Poughkeepsie, N. Y.—J. M. Candee.
Providence.—H. N. Fenner, E. F. Phillips.
Savannah, Ga.—T. P. Keck.
Springfield, Mass.—C. A. Nichols, J. W. Hyde.
Springfield, Ill.—A. L. Ide.
St. Louis, Mo.—J. A. J. Schultz.
Tokio, Japan.—Ichisuki Fujioka, M. E., S. Yashima.
Taunton, Mass.—D. L. Mitchell.
Trenton, N. J.—Fred. H. Angell.
Troy, N. Y.—J. A. Powers.
Waterbury, Conn.—D. L. Hungerford.
Washington.—C. J. Kintner, F. C. Royce.
Woburn, Mass.—W. R. Kimball, M. M. M. Slattery, F. Swift.

Convention Exhibits.

Interest was added to the meeting by many exhibits of electric lamps, apparatus, and supplies, in rooms of the Hotel Lafayette, where most of the members of the association were lodged. Below is a list of them:

LAMPS AND APPLIANCES.

Schuyler Electric Light Co.—Series incandescent lamps with automatic cut-out.
J. A. Powers—The Little—McDonald cut-out for incandescent lamps.
Sun Electric Co.—Incandescent lamps and distributors.
Bernstein Electric Light Mfg. Co.—Incandescent lamps and cut-outs.

ELECTRIC MOTORS.

Baxter Motor Co.
"C. & C." Electric Motor Co.
Edgerton Electric Motor Co.—(Exhibiting at their rooms, near the Hotel Lafayette.)

CABLES AND WIRES.

A. G. Day—Kerite Wires and Cables.
Standard Underground Cable Co.—Waring lead-covered cables.
Okonite Company—Okonite Wires and Cables.
Callender Insulating and Water-proofing Co.—Bitite wires and cables.
American Electrical Works.—Insulated wires and cables.

TESTING INSTRUMENTS.

Western Electric Co.—Portable set, consisting of galvanometer, bridge rheostat and 24-cell chloride silver battery.

MISCELLANEOUS.

Giles Bros.—Anti-magnetic watch shield.
E. P. Gleason & Co.—Electric lamp shades.
H. G. Osterle, " " "
A. K. Watt.—Electric light hoods.
Elgin Telephone Co.—Acoustic telephones.
J. H. Bunnell & Co.—Insulated pliers for electric light linemen.

Notes.

A very delightful sequel to the meeting of the association was enjoyed by about 50 members who came to New York in a special car, to dine with the Electric Club, Thursday, in acceptance of the invitation so handsomely extended to the association. The dinner was followed by a paper from Mr. Stephen D. Field on "Electric Railways."

The *Electrical World*, with its accustomed dash, captured a printing office somewhere in Philadelphia, on the first day of the meeting, and followed closely on the heels of the sessions, with a daily bulletin of the proceedings, distributing it freely among members and visitors.

The *Electrical Review*, kept hospitable quarters at the Hotel Lafayette, with doors wide open to all. It was a pleasure to be counted a frequent visitor there.

THE PARK ELECTRIC BRAKE TEST.

On December 30th last a test was made on the Chicago, Burlington & Quincy Railroad, at Burlington, Iowa, of the Park electric freight train brake. Briefly described the construction of the brake is as follows: A dynamo driven by a small independent engine is placed on the locomotive; the dynamo and engine are detachable, and weigh together about 400 pounds. Three wires run the length of the train and are connected by one coupling. The engine applies or releases the brakes by moving a lever on a switch-board. The current runs to the end of the train through one wire and returns through the centre wire. When the brake is released, which is done by the

Digitized by Google

same lever, the current runs through the third wire and returns through the centre wire. When the coupling at the end of the train is pulled apart, the wires automatically make the proper connection in the couplings, so that the current when applied will make a circuit the length of the train and through the centre wire; consequently the couplings require little attention. For applying the current to set the brakes, an eccentric is mounted on one axle of each car; the end of the eccentric rod is made to engage, by means of pawls, in ratchet teeth on the periphery of a cast-iron drum carried on the under side of the middle sills of the car. The drum carries a chain which is attached to the brake and levers in the usual manner. The passing of the current causes the pawl worked by the eccentric rod to engage the drum, which winds up the chain and applies the brake. A second pawl prevents the drum running back when that driven by the eccentric rod is moving back to take another stroke. When the current ceases the latter stops, but the former pawl holds the brake on. When the current is passed through the third wire, this pawl is thrown out of gear and the brake released. The brake is full on in a few revolutions of the wheel, and is applied simultaneously throughout the length of the train. At the trial, however, 10 to 30 seconds were required to put the brakes on the train of 25 cars. The results were, for a speed of 13 miles per hour, distance 132 feet; for 20½ miles, 462 feet; for 21 miles, 440 feet; for 31 miles, 1,090 feet, and for 38 miles, 4,664 feet.—*American Engineer.*

THE PRACTICAL REQUIREMENTS OF SMALL MOTORS.[1]

BY S. S. WHEELER.

It is a remarkable fact that not only have none of the small electric motors thus far put upon the market been constructed on the same principles as those of an efficient dynamo machine, but no attempts seem to have ever been made to copy large machines in the very features which are known to make them efficient and practically serviceable.

Any electrician, in looking at the motors heretofore offered to the public, can see at a glance why they cannot have a good efficiency, why their resistances are necessarily high, why they have to be run at too high a speed, or why their commutators will spark badly and quickly wear out, and why it is entirely out of the question to use them for giving power in thousands of cases. And yet, notwithstanding that these objections are almost entirely removed in large motors built exactly like large dynamos, no small motors have ever been manufactured before which are any approximation to the larger machines in these important respects.

Probably the most important reason why so little attention or electrical ingenuity has been given to the subject of small motors is that the energies and inventive faculties of electricians have for the past three or four years been devoted to the problems of the transmission of large amounts of power, and especially the propulsion of street cars, etc., which present great difficulties, but difficulties that electric motors are especially suited to overcome. The natural result of this prospective demand for such sizes and kinds of electric motors as this work will require, has been the diversion of the best electrical talent in this direction, and the consequence has been the production of such machines, almost perfectly adapted to the requirements.

Meanwhile the subject of small motors has lain comparatively unnoticed. Each isolated want is of less importance to the user and of less value to the dealer than in the case of a large motor; in other words, as the small motor to be successful must be cheap, and the power to be supplied is small, there is little money in each individual case, and it is only when the number of individual users gets to be large that the matter of small motors becomes a promising field. It does not follow, however, from the lack of attention bestowed upon the subject, that there is no field for such work; on the contrary, there is an enormous number of individual instances where an electric motor would certainly be used if it be just good enough to come within the requirements.

In addition to the ordinary uses where we regard a motor as simply the best means of obtaining power for a certain purpose, for example, the running of a large number of small machines in a factory, where the motors and feeding wire take the place of shafting and belts, there are many places where the work would not be practicable without one, and where a motor, therefore, would be said to create the use. Such are all uses of very small amounts of power where an engine cannot be run, and which are beyond the capacity of a man at a treadle. There is a large class of uses for power where a steam engine is not admissible, and where a good electric motor on a circuit is the only alternative, and in the absence of a motor good enough to be safe on an electric light circuit, or efficient enough to be run economically, all these industries have to be conducted in other ways, to avoid the question of small power distribution.

The response to the demand for electricity for lighting, has been the production of dynamos of ninety-five per cent. efficiency, a far better result than is obtained in steam engines, and conversely these dynamos can be used as motors with the same efficiency. But the result of the needs of electric lighting, in response to which demand these dynamos have been created, is that they are machines of large power, and so in these we have motors of large power without further change, save as to means of regulation.

Now why is it that we have not already had for some years motors of very small power, and reasonably near the same perfection of efficiency?

It is because a small motor while requiring the electrical construction and efficiency-giving features of a large dynamo to be equally efficient, cannot, for several reasons, be made an exact miniature of the large dynamo in mechanical construction.

If you want a 1,000 horse-power engine, you will get a Corliss engine, with elaborate valves, adjustments, etc. But if you want one of one horse-power, you will not get a miniature of the Corliss engine, requiring an engineer to take care of it. You will get a Baxter or an oscillating cylinder engine, with no external valve gear or adjustments, which will almost take care of itself. You must to make a small motor successful for such practical purposes as it is to be used for, reduce the complication of its parts and its liability to get out of order.

Of course this is realized by every one who has given the subject any consideration, but, nevertheless, the practical result has been that the only small motors thus far produced have been made apparently without any analysis of the difficulties to be met and any consideration of the means for overcoming them. Many of these motors have been so entirely unsatisfactory that they have been looked upon as little better than toys, and have reacted discouragingly upon the public.

Some of these motors, if placed on an incandescent circuit, for which they are intended, will burn themselves up. Others are of such very low efficiency compared with dynamos, that they require treble and quadruple the amount of current to give the necessary power. This is the principal reason why small motors, run from batteries, have not been more successful heretofore. The batteries have not been particularly bad, but the motors, instead of making good use of the current furnished, which is costly at best, have simply

1. Read before the American Institute of Electrical Engineers, New York, February 8th, 1887.

Digitized by Google

slaughtered the battery when pressed to do the work, by drawing four times the amount of current which would do the work, if efficiently used. I refer, of course, to the failure of the motor to give a counter E. M. F. when running, to which is due this inefficiency. The E. M. F. generated by a machine when driven as a dynamo, is the real test of its efficiency.

In order to get counter E. M. F. or magnetic effect, which is the same thing, and which is shown by running the motor as a dynamo and observing how much current it will *generate*, it is necessary to have a strong field, a large number of convolutions on armature, and high circumferential speed, all of which are interchangeable as factors; while at the same time the resistance of the wire and the speed of the armature must be kept down. The first is necessary so as to permit strong current effects to be produced and large power to be exerted when the motor is running slowly, as well as to reduce the loss from the internal resistance of the machine; and the second, to avoid high working speed, which is always undesirable, for mechanical reasons. It will be observed that all of these requirements tend to the enlargement of the machine, especially of the armature.

These considerations lead to the conclusion that it is better to make the armature a little larger proportionally than it is made in large machines, in order that our very small motor may still have the proper amount of wire, etc., in the armature, and be a true dynamo, capable of giving a proper E. M. F., instead of being a mere electro-magnetic engine. By so doing we also make the armature much easier to manufacture.

There is now before the public a small motor,[1] of which we have some specimens here to-night, in which the armature is enlarged radially, somewhat out of the usual proportion of armature to field, whereby the comparative strength of the field is perhaps reduced a little; but the armature capacity is increased in a much greater ratio, and consequently the E. M. F., or magnetic pull of the machine is large, and the internal resistance, as well as the shaft speed, are small. In addition to this departure from the usual proportion in order to meet the difficulties of small motors, there are a great many special features to increase the convenience as well as the efficiency of the machine.

As I believe this motor to be the first one on the market giving an efficiency corresponding to large dynamos, and at a price proportionate within 25 per cent. of the established prices for large machines, I think a description of it will be of interest. (I may say here that later on some tests will be shown, and an opportunity will be given of examining the motors and apparatus.)

The field magnets are of the simple horse-shoe shape, and the armature is a Gramme armature of comparatively large diameter and short length. The Gramme ring gives room for a large number of windings, with small mass of iron to be magnetized, and the large diameter, compared with the length, gives greater circumferential speed, with the same windings and mass. The cores of the field magnets are of best wrought iron, $1\frac{3}{8}$ inches in diameter and three inches long. The yoke and pole pieces are of equal section with the core, as is also the armature core, thus forming a magnetic circuit all around the horse-shoe and across the armature, of uniform conductivity. The yoke and ends of the cores are cut clean by machinery, and firmly bolted together, and the iron fibre of the pole piece continues up into the core, both being in one piece and of equal section. The non-magnetic base plate extends around underneath, and forms a clamp for fastening the whole motor firmly to the edge of a table, a point of great convenience.

The armature is built up of about forty semi-circles of thin sheet iron, riveted together with two long rivets, into a solid ring hinged on one rivet, so as to open on the opposite side to receive the winding. These thin laminæ of soft iron are separated by tissue paper, to prevent the generation of Foucault currents, precisely as it is done in the largest and most efficient dynamos. The complete armature winding, previously formed by automatic machinery, is slipped on to this split ring, which is then closed, the open ends of the half circles fitting into each other when brought together, forming a mortised joint, which is then secured by driving a final pin or rivet through them. When this hinged ring is closed, the core forms a hollow cylinder three inches in diameter, $\frac{5}{16}$ inch thick, and two inches long.

The armature winding consists of a flat wire or ribbon, wound on edge into a single helix, the full length of which equals the circumference of the armature. The commutator, which is of the disc type, consists of seventeen copper sectors riveted to a fibre washer. The latter is attached to a cylindrical wooden block which is turned true with the shaft of the motor, and to a tight fit for the inside of the ring, after the winding has been slipped on it. This block and shaft are then forced into the centre of the ring, until the outer extremities of the commutator sectors are brought within about $\frac{1}{8}$ inch of the winding on the ring. The claw-shaped outer tails of the sectors are then bent together, pinching tightly certain loops of the armature helix, which project out further than the main body, for this purpose.

These high convolutions or loops are then soldered to the commutator strips, making a solid and extremely simple and reliable connection.

The armature shaft is mounted in bearings, which are screwed to both sides of the pole pieces. The brushes are each held by a single screw, which also makes the connection with the leading wire, and, with the co-operation of the bearing plates, holds the brush at the proper inclination. The armature of this motor has room enough for a winding, such as described, composed of 204 convolutions and of sufficient conductivity to carry twenty amperes, half of the current passing around each side of the armature. Therefore, we may say that the magnetizing capacity of the armature winding is 2,000 ampere turns. Of course, the size of the wire in the armature may be changed to suit the circuit, so as to give a higher E. M. F. and less amperes, and still utilize the same amount of volt amperes within this limit. Thus we may substitute for the 204 turns on the armature, 408 turns of wire of half the size, and still get the 2,000 ampere turns, when used on a ten-ampere circuit. The field is wound so as to carry the same current. The company is at present winding its motors with three styles of windings; the style designated A is adapted to be used on 20-ampere circuits, such as the United States Co.'s arc light circuits; another style, designated type E, is wound for 10-ampere circuits, such as the Brush arc circuits; and the third style, designated L, is wound for 100-volt circuits or thereabouts, such as the Edison incandescent circuits.

In regard to the power and efficiency of these motors, I have found that when running at 1,500 revolutions per minute, a moderate speed for motors of this size, and, therefore, taken as the basis of tests, the 20-ampere motor, or type A, with 20 amperes passing through it, shows a difference of potential between its binding posts of 7 volts, 5 volts due to counter E. M. F., and two volts due to resistance. This means 140 volt-amperes consumed in the motor, or a little more than one-sixth of an electrical horse-power. Under these conditions a Prony brake shows a pull of five ounces on a one-foot lever; that is two foot-pounds per revolution, or about one-tenth actual horse-power at 1,500 revolutions per minute. The windings for other circuits give results to correspond. Therefore, when the motor is running with all the current it can carry, it uses about one-seventh horse-power of electrical energy and gives about one-tenth horse-power of useful power, or 50 per cent of the energy used, allowing for slight additional losses, which is about double the efficiency of any

1. See ELECTRICIAN AND ELECTRICAL ENGINEER, February, 1887, page 65.

Digitized by Google

small motor which I have examined. And this performance is with a current heavier than can be carried by other small motors. When running with about three-fourths of this amount of current, or about 15 amperes, the efficiency is considerably greater, reaching about 60 per cent. This is the best working load for the motor, because the loss by the resistance of the machine is less. But when we get down to about seven or eight amperes we find that the efficiency falls again, owing to the approach to the limit of weakness in the field. And when we reach four amperes, we find there is just field magnetism enough to turn the machine.

The loss of this initial current of four amperes in charging the field, is unavoidable, on account of the necessity of having enough mass of iron in the field to use the full two thousand ampere turns that the motor has, when fully charged, without bringing the iron too near the point of saturation, or, in other words, to make the motor large enough to use ¼ h. p. of current, without passing the point of saturation. Hence we see that if a motor is intended for use with a small current, it is better to make the field magnets of smaller diameter. This is another illustration of the difficulties to be met in making motors which will be good under varying loads.

In regard to its use as a generator, the motor with 20-ampere winding will give about 5 volts when running at about 1,500 revolutions per minute, and as its current capacity is 20 amperes, this means, allowing ¼ volt lost by resistance, 90 watts, or about ⅛ h. p. of electrical energy in the external circuit. That is, enough to light a 16 candle-power lamp. By changing the size of wire and putting on sufficient convolutions to get a high E. M. F., we get a generated current of 1 ampere and 90 volts, sufficient for a 16-candle light, with a consumption of ¼ actual horse-power.

As the motor was originally designed for domestic use in running sewing machines with a battery, the current from which is necessarily very expensive, great stress was laid upon designing it so as to make the very best possible use of the current, for the sake of economical running, and also to make the motor as small and light as possible with the capacity required.

This latter consideration led to the immediate determination to use the very best wrought iron, and it is only by making these necessary elements of good construction the first consideration in their manufacture, that a motor of this surprising efficiency has been produced.

In proof of the correct design and success of these motors, it may be interesting to hear that the semi-automatic machinery which was originally made for their manufacture has been kept in operation continuously for the last three months without interruption, and that already over six hundred of the motors are in use.

DISCUSSION.

Mr. S. F. Shelbourne in the chair.

Mr. P. Diehl—I have made experiments on electric motors, and have succeeded in making various types. One of these I have placed on the market; but since then I have made quite a number of improvements. I have finally come to the conclusion that the armature to be put in this motor should have more sections. The one which I have been making has only four sections, and the sparking is considerable at the commutator, but I have lately produced various motors, especially one to run sewing machines, placing the motor directly within the sewing machine—that is, putting the motor entirely within the sewing machine wheel, so that nothing can be seen of it. It is on the end of the shaft, directly connected without any belting. There is a great gain in that, as you can do away with the friction of belting, which is considerable on a small motor. In those motors which I produced before, the armatures were too small. I have found that the armatures have to be enlarged. I have built armatures on the Gramme type, and I found for a small motor about three inches to be the best size. I have made armatures in sections, of two halves, which are of easy winding; the field is about the same as the one I previously made. The motor I intend for a sewing-machine has a field magnet, in the inside of the ring, which gives very good results. The wheel and motor together weigh about five pounds. The wheel is only the housing for the motor. For fans and for such purposes I have built it in a different shape, but I use the Gramme ring. I have come to the conclusion that it is a better shape than the T armature.

Mr. G. W. Mansfield—I certainly would speak most heartily in commendation of the ingenious methods which the C. & C. company have adopted and devised for overcoming some of the most difficult problems existing in the early constructions of small motors. Perhaps the main reason why the Gramme ring was not used for small motors at an earlier date was that the armatures could not be wound cheaply enough. The wire had to be threaded in through the little ring and out again by hand. The method adopted by the C. & C. company has certainly overcome that difficulty in a very nice way. I think they have started in on a sound theory—that small motors can be built as efficiently as large motors—there is hardly reason, why they should not. We all know that small steam engines can not be built to operate so efficiently as large steam engines.

Mr. Wing—I would prefer to listen a little longer and to ask a few questions before undertaking to address the meeting at length. One of them is the question of batteries, primary or secondary, or any other kind. Are any here prepared to answer as to any of the existing batteries being practicable for long periods of time, so that the purchaser of a small motor can afford to run it? I have investigated quite a number, and, so far, none of them have proved satisfactory. I would limit the question to three horse-power, one horse-power will do. If I sell a sewing machine, or a fan, or a lathe, or anything else, I want to know commercially how long I can guarantee that battery to run and how much it will cost to run it per day, per week, or per month.

Mr. Wheeler—I might perhaps give you some figures about the batteries we are making; but I think that in respect to the cost of running them, I should refer you to Mr. Crocker, who is one of the mechanical experts of the company, and who has more figures in his head than I have. I might say, however, that our battery is an electro-poion battery, having no porous cup. Instead of using carbon plates we use pencils. We use the regular electro-poion fluid, except that we supply the chemicals in solid form. Here (exhibiting) is some of the material, and if we add pure water to that and analyze the solution, we will get almost exactly what electrical dealers call electro-poion fluid. The amount of chemical energy in this solution is just the same as it is in the same volume of the ordinary electro-poion fluid.

Mr. Wing—I have found this difficulty in all those with which I have experimented, that when you come to take them commercially, there is the inconvenience of emptying the jars and replacing them.

Mr. Wheeler—Due consideration of that point has led to the production of a battery jar which has a very suspicious appearance (exhibiting a porcelain jar provided with a handle. Laughter). As that has about a tenth of a horse-power in it, I do not want to upset it.

Mr. Mailloux—How many sewing machine hours has it got?

Mr. Wheeler—It has got about six sewing machine hours. The electromotive force is 3 9-10th volts; the internal resistance is about 5-100ths of an ohm. When you begin to use it, it rises to about 15-100ths of an ohm, when the solution is mixed up with the acids of the reaction, so that the fair average is about 1-10th ohm internal resistance, and the capacity of the battery is 12 amperes. It will keep on furnishing 12 amperes without declining until the chemicals are all used up. It does not furnish 12 amperes to run a sewing machine for six hours, because a motor, when running a sewing machine, will use only about 8½ amperes.

Mr. Wing—Suppose you want to run five or six hours during the day and eight or ten hours at night, how many cells would it be necessary to have and how long would those cells last without replenishing?

Mr. Wheeler—Do you mean continuous running? You know if you give the machine to people, they will say that they use it continuously. The facts are that they sew for a minute; then they stop to shift the direction of their seam, etc., and the battery is not drawn upon. I have to make that distinction, because an absolutely continuous run is a very different thing from a "human being run," so to speak.

Mr. Wing—I am getting at the actual run, four hours during the day and an eight-hour run at night.

Mr. Wheeler—I think you would have to have jars of about twice the size of this. Of course, if you were not going to do the work at any greater rate than this, you could use the same solution and simply have larger jars. If I were going to do it, I should have another pair of jars ready, and slip them in when the first were exhausted. It is only a question of having enough solution there to keep it up for that length of time.

Mr. Wing—My experience is that I cannot sell a machine to run by jars in the ordinary form for the simple reason that they have to be changed too often, and it is too much work to change them. In running a sewing machine, as Mr. Wheeler observes, they run a minute and then they do not run a minute, and sometimes they do not run for ten minutes; but when you come to put this same motor upon a fan or lathe or machine that requires continuous running, the case is otherwise; the fan is probably

Digitized by Google

the worst thing you can put on to a motor, because it is a dead pull from the time you start it. Now, we sell fans largely for that purpose, and they want to be run about four or five hours for office business. Many thousands could be sold for ventilation of private residences, sleeping rooms, and the like, if we could get a battery, or if we could get the power at a moderate price to run those motors during the sleeping hours, say eight or ten hours, but it must be a steady run.

Mr. Pendleton—I think if the circuit were established from central stations, there would be no difficulty in running either a fan or sewing machine satisfactorily. At the present time you are obliged to do what you can with the best batteries in existence at the present day.

Mr. Curtis—I think the kind of fans Mr. Wing refers to chiefly are fans that require more than half a horse-power to drive them.

Mr. Wing—No sir; a thousand could be sold for that purpose at about one-eighth to one-fourth horse-power, for sleeping rooms. This motor has got the power for that purpose, as I can see from the speed at which it runs the fan here. One-eighth or one-fourth of a horse-power will do very well for sleeping-room purposes, and thousands will be sold for that alone.

Mr. Curtis—The power of one of these batteries is about 1-40 to 1-50 of a horse-power. Now, if you want 1-10 of a horse-power you would require four to six of these batteries. A tenth of a horse-power on a small motor is a good deal more than you would expect. When we were running it here, we were running from the Edison circuit, and we were taking about as much current as one of these lamps takes. We were taking a little more than a tenth of a horse-power.

Mr. Wing—A tenth of a horse-power is ample for the purpose I referred to.

Mr. Curtis—The question is whether somewhat less than a tenth would be enough.

Mr. Wing—It would be for smaller rooms.

Mr. Curtis—When we took up the problem we found that there was not any battery in the market which, unless we used a good many cells would give anything like the necessary current. Now, the only way to get the power out of that is by fulfilling two conditions. In the first place you have got to have large plates so that you do not draw a heavy current over a small surface. In addition to that, you have a very low resistance. As soon as the resistance of your batteries comes up, you have got to add cells. The resistance of the two cells is only 1-20th of an ohm, which is ridiculously low for a battery of that size. There is not any battery made to-day which is as low as 1-20th of an ohm for *one* cell, except a very large plunge battery. Now, the only battery which would take the place of this, that could be used to give the same volts and amperes before we got this up, was something like a Bunsen battery or an ordinary plunge battery. The difficulty with the plunge battery was that it would not maintain a current; there was no circulation of the liquid; and then if we put the plates nearer together, the circulation would form the sulphate of zinc on one plate and form the water on the other plate, and we could not maintain the action, and you had to stop and give it a rest and then start off again.

Mr. Wing—That has been my experience in all that I have tested.

Mr. Curtis—That is eminently the case in any form of battery where provision is not expressly made for circulation. In this battery we can get from about a square inch of surface about an ampere. You take a battery with a porous cell in it, or an ordinary plunge battery, and it will have perhaps 12 square inches to the half ampere. This battery will give from five to ten times as strong a current for a given area of zinc as any battery I know of. We seem to have got as near the limit of lowness of resistance as possible; unless you can lower the specific resistance of the solution, you cannot bring your plates any nearer; there is nothing intervening which you can take out and you have got the resistance as low as you can get it.

The only way in which you can get power enough out of this kind of battery to give you one-tenth of a horse-power is by adding cells or making larger cells. Now, you can do that easily enough. But nevertheless it involves having the cells four times as large or having four times as many of them. Then the domestic conditions come in; perhaps you can use it, perhaps you cannot. There is not any battery at all that it is worth while to talk about for a half horse-power, entirely irrespective of the cost of solution. The solution is quite a costly thing, anyway. The cell we employ will give a fortieth of a horse-power continuously for, say, six hours. That costs one charge of solution, and one charge of solution costs about 30 cents. So it costs 30 cents for six hours. There is no difficulty in obtaining all the power you want if the electric light circuits are there. We anticipate that all cities are going to have arc or incandescent circuits for domestic use, and we propose to put our motors on those circuits. You can put one of these motors in the place of one of these lamps here, as we do now, and it will give you a tenth of a horse-power.

Mr. Wing—Do you intend to build your motors for arc circuits?

Mr. Curtis—Yes; we have some already built. They are boxed up to protect them, that is, to protect the people outside of them from touching them and getting a shock.

Mr. Wing—Do you have to have any resistance coils?

Mr. Curtis—We have a shunt which controls them. They have a multiple arc with a variable resistance.

Mr. Wing—I have understood that you have already put some on the Brush circuit. Have you arranged with them as to charges?

Mr. Curtis—In some of the cities we have. We have not arranged in New York yet. The Brush people are trying it now. Mr. McGrath, who is superintendent of the district in New York, is trying it for his own station. I believe he says that they are just what they want for their circuits.

Mr. Wheeler—Mr. McGrath reports 45 per cent. efficiency on his circuit with this motor.

Mr. Wing—He told me they were prepared any time they got a motor that was satisfactory to them to put it in. I understand that in Baltimore the Brush people have agreed to furnish the Baxter motor with a horse-power at five dollars a month. They are doing it right along all the time, for one horse-power or ten little ones at the same rate. They are putting them in a great many places where they are using sewing machines.

Mr. Martin—In Philadelphia the Brush company are running about 200 small motors on their arc circuits.

Mr. Mailloux—I had recently occasion to experiment with various forms of batteries while conducting some researches with the new exciting liquid which has come into the market lately under the name of "coquimbite," and while experimenting with it, I had occasion to use some batteries which are made in Philadelphia by Partz, called the Partz acid gravity battery. It is a square cell in which the carbon is placed on the bottom. The carbon has a corrugated surface. He has one form which is simply a zinc, as in the gravity cell. In the other form, he has a porous cup with the zinc inside, and I have found that when the liquid was at the lowest specific resistance possible, the total resistance of the cell, carefully measured, was as low as $\frac{1}{100}$ ohm, and, consequently, anybody might think that you might obtain a very large volume of current; but unfortunately as soon as you close the circuit you find that there is only a very small current, comparatively speaking. You may get between five and ten amperes; but even that not for a great length of time, simply because you have the counter-electromotive force of polarization which immediately reduces the available electromotive force. I am told they are using these batteries with great success for dental purposes. They generally run them in series of three or four, and do not ask such a great rate of current of them and depend upon greater electromotive force to get a greater number of watts necessary. The cell is certainly a very convenient one, so far as construction goes, because it is so made that it will run without care and comparatively very little attention, for months. I have not carried out my experiments with the battery with the Partz solution, and consequently I cannot tell how long it will last; but it occurred to me that it was a very convenient form of cell, particularly for in-door use, office work, and places where the battery is to be tried for a certain length of time and where it is desired to have a battery that does not require much looking after. I succeeded in getting four amperes out of a coquimbite solution, and I was led to reason from that that possibly the other would give a higher current, and I think that some party I have met told me that Mr. Partz himself was using them a great deal for motors where the current continuously was from two to ten amperes.

Mr. Curtis—Dr. Partz tried it in my office and it would not maintain more than three.

Mr. Martin—This whole motor question resolves itself into a question of current. If once we have the motor, as we have, the question comes, where shall we derive the current to drive it? It is very apparent, I think, from this discussion, that the day of the primary battery in driving motors is not a very long one. Where shall we get the current then? We can get it largely from the arc light circuits; we can get it from the incandescent light circuits. There are 700 to 1,000 motors on arc circuits and a great many on incandescent circuits. Mr. Sprague, for instance, has a large number of small motors in Boston, 25 or 30, at least, running on the Edison three-wire system. But in order to put motors into residences and have them running when people want them, you want to have a current that is available all day long in a great variety of places. Hence, to get that current, it seems to me we must in the last resort fall back on the secondary battery.

Mr. Wetzler—Regarding the efficiency, not theoretical, but in a practical sense, I would like to call attention to a fact in regard to the construction of the armature of a motor. I am acquainted with a very well-known electrician who had started out to make a small motor of large efficiency, one which should approach the efficiency of the larger motors. He started out with a solid armature of the Siemens type. He got, I believe, 15 or 20 per cent. He tried all sorts of winding, etc. It occurred to him that it might be well to laminate that armature, which he did to a certain extent, and he obtained 10 to 20 per cent. more

Digitized by Google

efficiency. He kept on increasing the number of his laminations until he reached 60 per cent. Consequently, I would like to point out that the efficiency of a small motor must be looked for to a considerable extent in the lamination of the armature. I see in the armature before me that the attempt has been made; but it strikes me that it could be improved upon, if the suggestion is allowable. It seems to me that there may be some chance of the current getting across these sections.

Mr. Curtis—We made one test. We mounted one of those rings on a wooden block, without any winding of the armature, and ran it at a high speed, and we found that whether you turned the field on and off or not, that is, whether it was revolving in the magnetic field or not, made only a very small difference, and that was with an armature in which the laminations were only half as thin as they are there.

Mr. Wetzler—You had no windings on that at all.

Mr. Curtis—No windings.

Mr. Wetzler—You cannot say, then, that the conditions were exactly alike. Did you ever try a solid core with your actual windings on it? That would be a crucial test.

Mr. Curtis—No; that would be so vastly different from a solid core. Until you get up to a certain point the efficiency runs up very rapidly. Beyond that point the Foucault currents are so small that it does not pay to carry them much further. We considered the thing very carefully and I do not believe that there is over five per cent. lost at the very outside, by Foucault currents.

Mr. Wetzler—You will also remember that some time ago Mr. Mordey pointed out distinctly that the loss in the motors was due to that very cause, the Foucault currents. There is another point I want to bring up, and that is, do not you gentlemen consider it advisable to have some arrangement for reversing the motor? For many applications it is desirable that the motor should run in the opposite direction.

Mr. Wheeler—Do you mean momentary reversal?

Mr. Wetzler—To run a machine in either direction.

Mr. Wheeler—You can do that; you can change the field connection for one thing.

Mr. Wetzler—I mean to have your motor on your lathe or work table, and be able to turn a switch or any other mechanism, and have the motor run in the opposite direction.

Mr. Curtis—We have not had any demand yet for such a machine, and the principal purpose that has occurred to us for that kind of thing is for use on a boat.

Mr. Wetzler—I can see very well that there would be more than one application for that kind of motor. For instance, a dental lathe would want to be reversed.

Mr. Martin—I have had dentists ask me if I knew a motor of that type.

Mr. Curtis—One point about these brushes is that they are arranged so that the armature can be turned in either direction without destroying the brush.

Mr. Pendleton—I had some years ago a surgeon of this city making some experiments with an osteotome in my laboratory for the purpose of testing the power to be received from an accumulator, and for that purpose he brought down with him tibiæ, feet-bones, and so forth, and had his little saw attached to his surgical instrument which operated very satisfactorily; at least he said that he had never been able to get such results from any primary battery, and he had spent several thousand dollars in trying to perfect a system suitable for his purposes. I noticed that his instrument got upon a dead point several times and I asked him how it was. He said it was the best he could find. I then furnished him with a motor which has attracted some little attention, although it has never been put on the market to any extent. I have received letters from Paris in regard to the cut of it, which was published by the *Electrical World* some time ago. That little motor fulfilled its purpose and it was simply the commutation of two brushes upon a three-pole armature with the usual circuit, so that there was a continuous current through the two circuits of the armature, and the polarities gave on the three-pole armature all the attraction and repulsion that was capable of being derived. I finally conceived that it would be a benefit to use discs of thin iron, and my experience in the matter fully coincides with the remarks made here to-night. There was an efficiency of at least 25 per cent. merely from replacing the cast iron by the wrought iron. In regard to the loss by Foucault currents mentioned, this ring traveling in the periphery of the armature would not suffer from Foucault currents as much as the ordinary armature which is placed directly upon the shaft and having the speed of the periphery so much higher than the iron nearer the shaft. In that respect I should hardly think that 65 per cent. would be an overestimate. In regard to insulation, an insulation by peroxidizing this iron might be sufficient, instead of taking up the space with paper. These little motors are now becoming very interesting, and their importance will be appreciated so soon as we can get the current to introduce them generally; and, when the time comes, do not forget that the secondary battery will be a most valuable apparatus to regulate and govern these motors and economize at the same time the power which would be lost in any other method of governing.

NEW YORK AND VICINITY.

New Legislation for the Subway Commission.—Another State Commission Proposed.—Distribution of Telegrams in the Western Union Operating Room.—The Electric Motor Business.—Steam Heating and Power in Newark.—Sprader, of New Brunswick, Against Overhead Wires.—Mr. Edison's Health.

ONCE more the state legislature has been called upon to patch up its previous work which was supposed to be sufficient in itself to have caused all wires to be placed underground long ago. The commission was authorized to "devise," but it could not execute its plans without money, and the legal plan for obtaining money was in itself so defective that funds were not forthcoming even for the ordinary running expenses of the board. It would naturally be supposed that a law of this nature would provide effectually for drawing salaries if for nothing else. With the opening of spring, however, a very extensive programme of work has been proposed, and the telephone company at least will be ready to place its wires out of the reach of sleet storms, which twice this winter have ceased just in time to prevent serious damage to overhead wires of every kind. Provision has been made in a bill introduced in the legislature by Mr. Coggeshall, for creating a state board of three commissioners which shall have control of the telegraph, telephone, electric light, and district messenger companies.

The mechanical system for distributing messages in the main operating room of the Western Union company has now been in successful operation for over a month, and is giving perfect satisfaction. It is similar in principle to the cash carrying systems which have been introduced in many of the large retail stores.

The electric motor business is gradually assuming greater importance in the eyes of those who are already engaged in electric lighting, although they are very cautious in venturing upon a field which appears somewhat doubtful in its financial returns. Those who are familiar with the subject are however exceedingly confident that it offers greater inducements than the electric lighting industry; because of the almost unlimited field, while arc lighting at least cannot be extended beyond a very small percentage of the total amount of artificial illumination. The Third avenue surface railroad company will certainly make a mistake in equipping its line with a cable system when electricity stands ready to offer a far more complete solution of New York city's serious problem of rapid transit. When so great an expense is incurred a radical improvement should be made, and judging from personal observations and the testimony of careful observers, the cable is by no means so important an advance over horse power, as electricity bids fair to be.

The Newark Steam Heating and Power Company has purchased the old Nugent factory on Halsey street, Newark, and will put up new buildings and a large battery of boilers for the purpose of supplying steam power to the block bounded by Broad, Market, Washington and William streets. It is probable that the Edison company will occupy the rear of the premises. Some opposition has been manifested to the granting of franchises to the steam company without compensation to the city, as experience has shown that none of these companies devote sufficient attention to replacing the pavements in as good condition as before tearing them up.

Mr. P. Vanderbilt Sprader, of New Brunswick, N. J., is not in favor of granting unlimited privileges for electric wires, and expressed his determination to spend $5,000 if necessary, in order to secure the removal of wires which had been placed on buildings, so that they swung over his land. Mr. Sprader in a card to the local paper, calls the people to arms with the following vigorous appeal:

> Is the Electric Light Company, through their servant—that dirty, miserable liar, Wilson Stout Howell—to ride over the people and trespass on their property? Do the directors of this company understand and approve of his method of doing business? I understand that this is not the first time he has carried his wires over other people's land by sheer cheek and lying. Is he a worthy officer of a worthy company?

The wires have since been removed, and Sprader rejoices that he still lives in a free country.

Considerable space has been occupied in the daily papers, recently, regarding Mr. Edison's breaking down in health. It was reported that he was insane, and that no hopes were entertained of his recovery. It is well known among his friends that his life is devoted to inventing and experimenting. It is his recreation as well as his occupation. He has for many years drawn heavily on his stock of vitality, and nature has doubtless rebelled against it. He has not been as careful of his health as he should, and is paying the penalty. If he heeds the warning and cuts loose from laboratories, doing just enough to amuse himself, no doubt he will recover his full strength, but he is of course considerably older than when he first entered upon his career of invention, and should avail himself of his good fortune in being able to seek a change of scene, which will no doubt be of great benefit to his health.

NEW YORK, February 21st, 1887.

PHILADELPHIA.

The Electric Light Convention.—Suit of the Brooks Telegraph Construction Co. against the American Telephone and Telegraph Co., et. al.—Electric Railway Notes.—The Reading & Pottsville Telegraph Co.—Action of Councils on Electric Privileges.—Death of Mr. Joseph Christie.

SELDOM has a finer looking or more intelligent body of men assembled in this city than was gathered February 15th, in the annex to the Union League at the Convention of the National Electric Light Association. As an adjunct there was an exhibition of incandescent lights and electric motors in the Hotel Lafayette, where the officers and members of the convention made their headquarters. Not less than 156 firms, corporations and individuals are identified with the association. All the principal cities were represented.

In the convention sat two Japanese gentlemen. One of them, Mr. I. Fujioka, formerly professor of electrical engineering in the Imperial College, Tokio, visited this city during the Electrical exhibition in 1884. The other, Mr. S. Yoshima, is president of the Electric Lighting Company of Tokio.

A bill in equity was filed a few days ago in the United States Circuit Court on behalf of the Brooks Telegraph Construction Company (Limited), against the American Telephone and Telegraph Co., H. A. Pitcher, the manager of the same, and the American Telegraph and Telephone Co. of Pennsylvania, asking to have the defendants enjoined from the making of an alleged infringement upon the complainant's patented improvement in telephone circuits. The plaintiffs claim in the bill that they bought the exclusive right, under a patent held by David Brooks, the inventor, to make and use metallic circuits throughout the United States for a term of seventeen years from February, 1881; that they have expended large sums of money in perfecting the system, but that the defendants are violating this exclusive right. It is claimed that the rapid application of long-distance telephones to business purposes renders the prospective value of the ownership of the metallic circuit to be contested in the courts second only to that of the telephone itself.

It is reported that the Philadelphia Traction Company has finally successfully experimented with electricity as a motive power for their cars. The report is that motors are already being put in a number of the cars to supersede the cable in the spring, and that by degrees, if the new motor comes up to the expectation, it will be gradually introduced over the Traction system, beginning with the Darby Branch and other West Philadelphia lines that are not now cabled.

Reading railroad officials doubt if president Corbin contemplates a lease of the Reading and Pottsville Telegraph Company to the Western Union Co. as rumored. The receipts of the company are a considerable item of profit. The property is bonded at about $200,000. "It is usually unsatisfactory for a railroad company to conduct an express business, but there are many conducting extensive telegraph lines with profit," said a railroad man yesterday, "and there is no good reason why the line should be leased."

On February 3d, the electrical committee of councils reported favorably a supplementary ordinance to give the Penn Electric Light Company, of New Jersey, extended privileges. The board of highway supervisors also approved an amendatory ordinance authorizing the Penn Electric Company to construct additional conduits on Chestnut and other streets, the plan having been approved by chief Walker, of the electrical department. A similar application from the Edison company was postponed, in the absence of the necessary papers. The electrical committee of councils have passed favorably on an ordinance providing for the erection of 155 additional street lamps, to be located in various parts of the city.

The death of Mr. Joseph Christie, which sad event took place on the 9th day of the present month, will be greatly regretted. Mr. Christie was well known in telegraphic circles throughout the country, and at one time was correspondent for the ELECTRICIAN AND ELECTRICAL ENGINEER, in this city. Since, and until the time of his severe illness, he has been connected with *The Electrical World*, for which journal he performed valuable service.

PHILADELPHIA, February 17, 1887.

BOSTON.

The Telephone Case at Washington.—State Regulation of Telegraph and Telephone Companies.—The Legislature Invoked to Introduce an Electrical Police and Patrol Wagon System in Boston.—Gas Lighting Companies Seeking Franchise for Electric Lighting.—Electric Light Notes.—A State Electric Light Association.—The Boston & Albany R. R. try Electric Lighting in their Cars.—Ball of the Telegraphers' Mutual Aid and Literary Association.

THE suits against the Bell telephone at the Supreme Court, Washington, D C., have been the excitement for the month, not only in all the country, but especially in Boston, where the company "is found." There is more news abroad than there is at home in the matter, exemplifying the old law, if you want the news go away from home.

The sun is shining brightly just now for the legal haymakers, and it will take a good many telephone rentals to square their bills. The expenses of the Bell company are of course much larger than those of the appellants.

The Massachusetts legislature are not yet satisfied to allow the telephone business to live like other kinds of business; steps have been taken toward further legislation concerning the regulation and conducting of telegraph and telephone companies; as to placing telephone companies under the supervision of the railroad commissioners; as to establishing uniform charges for the use of telephones; for further limiting the amount of stock telephone companies may hold in branch companies; limiting telephone charges to $3 for each instrument.

In the state senate, on the 21st ult., a petition was received in aid of the petition of the police commissioners of the city of Boston, for authority to introduce and maintain an electrical police and patrol wagon system, signed by many prominent citizens, firms and corporations, and on the 4th inst. the committee on cities had the subject before them. Augustus Russ and Lewis G. Farmer appeared in behalf of a committee of citizens in favor of granting the petition, and city solicitor Bailey appeared for the city. The police commissioners and the captains of districts 1, 3, 5 and 6 were also present. Commissioner Whiting explained to the committee that the board, having failed to induce the city of Boston to move in this matter, had come to the legislature. He spoke at length of the advantages possessed by the system, saying that it would be more than an equivalent for an additional 100 or 150 men on the force. It was utterly impossible to get any bill for the system through the city government. When the commissioners went into office there was a restriction on the department's appropriations against the use of money for this purpose; this year they included an amount for the system in their estimates, but it was stricken out by the mayor. An appropriation of $200,000 would be sufficient, and no additional policemen would be needed. Mr. Whiting said that the adoption of the police signal system was recommended in three annual reports by the commissioners whom the present board succeeded. The system in use at South Boston was placed there at no expense to the city, and the commissioners are not under obligation to purchase that system in case it proved favorable. Mr. Whiting submitted testimony relative to the efficiency of the system in Baltimore. Commissioner Lee said that there was an average of one policeman to three miles of streets, and that it was utterly impossible for an officer to cover this area efficiently. It would be impossible to call the force together in less than three hours. Under the proposed system the whole force could be got together within three-quarters of an hour, fresh and ready for work.

Commissioner Osborne said the legislature deemed it expedient to take the control of the police from the city council, and he held that the board has now a right, if it wanted to test the matter in the courts, to introduce the system. The board came to the legislature because the city refused to pay the expense; because the city government was diametrically opposed to the metropolitan police commission. He suggested that the expenditure might be met out of the money received from liquor licenses. Last year $110,000 was collected in excess of any previous year's license receipts, while there were at least 500 less tippling places. The system could be introduced, he thought, at an expense of $150,000. The Gamewell people are ready to place their system here on trial. Captain Eldridge, of division 6, and other officers testified to the efficiency of the patrol wagons. The hearing closed with an elaborate argument by Mr. Russ for the petitioners.

There was a large gathering of parties interested in gas and electric lighting in the blue room on the 2d inst., when the committee on manufactures gave a hearing upon the petitions of several gaslight companies for authority to furnish electric light and power. It being understood that a general bill would be favored by the committee, some of the gas companies raised the point that certain special interests would be hazarded; and the representatives of the electric light companies objected to the subject-matter of the petitions upon the ground that the gas companies, so far as appeared, were mainly desirous to keep the electric light companies from extending their business. If a general law were passed, it should contain a proviso that the gas companies should not be authorized to furnish electric light where it is already furnished by another company. At the suggestion of senator Jefts, the committee adjourned for one week with the understanding that in the meantime the parties in interest should submit a general bill. Matters which cannot be included, it was said, might be met by special legislation.

On the 11th inst. the committee on manufactures continued the hearing in regard to a general law authorizing gas companies to furnish electric light and power. Mr. W. E. L. Dillaway submitted a new draft of the bill presented by him at the former hearing. The changes are mainly matters of detail. He submitted an additional section providing that after a gas company has begun to furnish the electric light, it shall file a statement with the gas commissioners, telling what it is doing, what system it is using, and what prices it is asking. He had omitted the

Digitized by Google

provisions contained in Mr. Greenough's bill relative to setting up poles, and that the mayor and aldermen of cities and selectmen of towns *shall* give permission to set up such poles, as those matters are fully covered by the statutes. The setting up of poles is a matter entirely discretionary with town and city officers. Mr. Goodrich, on the contrary, said that the local authorities are bound to furnish locations unless they are shown to be hindrances to public travel. Mr. Lane, of Leominster, protested in the name of the municipalities against permitting private parties setting up poles and running wires without the consent of the local authorities. Mr. Lane appeared for the selectmen of his town, of which he is chairman; but he was also a director and clerk of the Leominster Gas Light Company.

Mr. Samuel L. Powers of Newton, appearing for the Cambridge Electric Light Company, said this was a contest between the forty electric light companies, representing $3,500,000 of capital, on the one side, and the gas companies in nearly every town and city in the state, with a capital of $12,000,000, on the other. The committee is only concerned in so far as the interests of the people are concerned. Whenever the price of gas had been reduced it was owing to the competition occasioned by the presence of an electric light company. As is shown by the returns made to the gas commissioners, some of these gas companies paid dividends last year of thirty-six per cent. They must be content with smaller dividends, as will certainly follow if this matter of electric lighting be left open to competition. The gas companies, seeing the growing favor in which the electric light is held, are intent upon monopolizing the business by the utilization of their extensive plants and the power of their immense capital. They were afraid of the opposition of the electric light companies, which could furnish the light as cheaply as the gas companies, notwithstanding claims to the contrary. Testimony corroboratory of these statements was submitted by Horace B. Parker, president of the Newton Electric Light & Power Company; E. H. Ashcroft, of Lynn; Reuben Arey, master mechanic of the Naumkeag Steam Cotton Mills; and others. The hearing will be continued.

Of late there has been considerable discussion by members of the Somerville city council as to which company should furnish electric lights for the streets of that city. It is not unlikely that the Cambridge and Charlestown Gas companies, which now furnish the gas, will be awarded the contract for electric lighting.

An association has been formed, composed of most of the Electric Light companies of Massachusetts. The organization is to be known as the Massachusetts Electric Lighting Association, and the following gentlemen are its officers: President, James F. Almy, of Salem; vice-presidents, D. L. Mitchell, of Taunton and Jerome W. Hyde, of Springfield; treasurer and secretary, H. Burr Crandall, of Boston; executive committee, Edward S. Sears, of Boston, H. H. Fairbanks, of Worcester, and J. D. Flint, of Fall River.

On the evening of the 4th instant the Electric Light company of Woburn put into operation a Brush machine of 45 arc lamp power. All of the lamps have not yet been connected with the machine, but a number of them which were in working order were lighted on Main street. They gave great satisfaction. This company has had the incandescent light in operation for nearly a year. It will soon add to its plant power for lighting dwelling houses.

The Boston & Albany Railroad managers are experimenting with a system of lighting its cars with electricity. The first test was made on the 4.45 train on the Circuit road. The car No. 90 has been fitted up with 10 incandescent lamps of 25 candle power, while each platform is lighted by another lamp. The power or light is derived from storage batteries or accumulators placed in suitable receptacles under the car, and these storage batteries are said to be sufficient to supply the light 8½ hours. The Julien Electric Company, of New York, equipped the car.

The Electric Lighting and Power Company on the 26th ult. entertained 150 gentlemen of Newton at their light station on Crafts street, Newtonville. The speeches made after a collation had been served showed the general sentiment to be in favor of having the streets lighted by electricity.

The Lynn Gaslight Company contemplates establishing an electric light plant.

The Telegraphers' Mutual Aid and Literary Association held its second annual ball on the evening of the 4th inst., at Odd Fellows' Hall. There were about 400 couples present, and among the guests were prominent officers of telegraph companies in Boston, New York, Providence, Springfield, Lowell, Woonsocket, and other places. Congratulatory despatches were received from many places, including one from London, Eng. Music for dancing was furnished by the Boston cadet band. Mr John D. Mulloney was floor manager.

Electricity appears to be the coming "horse" that shall at some day not far distant be the motive power of the street cars of Boston. Officers of the different railroads have for several years given the matter much attention; at one time it was thought that the cable system, in successful operation in several cities, would be introduced here, but the rapid progress made by electricians in the way of perfecting motors has drawn to their work the careful investigation of railroad men, and some who had thought favorably of the cable system are now waiting for the results of experiments with electrical motors.

The opinions of several railroad presidents have been obtained by the *Boston Herald*. President Calvin A. Richards, of the Metropolitan Railroad, said: "I am thoroughly sincere in my expressed opinion that some other power will take the place of horses in the near future for moving Boston street cars. Electric roads are now running with more or less success in several cities. While the conditions regarding snow and ice are not precisely the same in any of them as prevail in Boston, the experts profess confidence in their ability to overcome all obstacles. Personally, I consider the 'storage battery' system one of the best, as it calls for no alteration of the roadbed, and applies its power directly to the wheels of the cars, thus obviating the great waste which must result from using any system where the power passes a long distance through a conductor from a central station. The apparatus will be out of sight under the car, and its extra weight of 2,500 pounds, instead of being an objection, will aid in securing necessary 'traction.'"

In regard to the cable system president Richards said, "I don't believe in it. I have investigated the system pretty thoroughly, and seen it operate in most of the cities where it is in use, and it does not impress me favorably. I am even sceptical as to its superior economy as compared with horses, though those who use it declare that it is much cheaper. It costs an immense sum to put in the plant. It would take a million or two, to begin with, to alter the Metropolitan road so that we could use it. Expensive machinery is required, and the cables are costly and easily broken. Some of the western roads run two cables, in order to make lightning changes in case of accident. The 'grippers' wear out fast."

President Hersey, of the South Boston company, said: "The cable seemed to me a great improvement, though having several objectionable features; but recent developments in electrical appliances are such that I should not think of putting in a cable road before some of the new plans have been tested."

President Cummings, of the Cambridge Railroad, and president Whitney of the proposed Suburban Street Railway, also spoke favorably of the prospects of electrical motors for cars.

BOSTON, February 17th, 1887.

CHICAGO.

The Old and the New in Fire Alarms.—The Telephone Suits.—The City Electric Light Plant.

THE old and the new forms and methods of fire alarm matters in Chicago, show what an improvement has been made—what an advance the column of the electric army has made—in a comparatively few years. True, from 1863 to 1887 is nearly a quarter of a century; but steamboats go but a very little more rapidly than they did in the sixties. Whether we grant that electricity in this particular branch has more than kept pace with general advancement in the arts, in science or manufactures, the following from an interview with Prof. Barrett, will have a certain interest.

"It was in 1863," said Prof. Barrett the other day, "that I first went on watch in the tower. It was on top of the old court house on Clark street, and was about 150 feet high from the ground, I guess. Our room was near the top, and was walled around with glass, so that the whole city could be seen. Above us was the belfry, and we used to ring the bell, that was cut up into so may relics of the big fire, by means of a lever. The city then was divided into six districts. When a fire was discovered, the watchman would first strike eight on the bell and then follow with the number of the district in which he thought the blaze was located. All the engines were supposed to pass the court house on their way to a fire, and as they passed the drivers would look up toward the top of the tower where the watchman displayed a red flag pointed in the direction of the fire. You would be surprised to know how accurate our alarms were. We very seldom sent an engine to the wrong location. Of course the city was very small then, and we knew and could see nearly every house. Nevertheless, it required a pretty sharp eye to see where a fire was on a dark, cloudy night, especially during the winters, when the frost coated the glass. We had a rustling fire department though. It was as good as any we have ever had. I stayed in the tower till the fire alarm telegraph system was adopted in 1865, when I was put in the office. When I went on there were two brothers there named Joyce, but they left and other men took their places. The job was often given to old firemen. One of these afforded fun for the whole town for a week. He napped at his post during the evening, and when he awoke the sky was all aglare in the east, and he thought Wabash avenue was burning. He turned in an alarm right away, and all the men went down on the lake shore looking for fire. They found nothing except that the moon had risen and was still looking red and hazy through the fog. The moon fooled the watchman. After a time the city got too big for such a provincial system, and the smoke from the factories obscured our sight. Then the fire alarm

Digitized by Google

telegraph was introduced. Old U. P. Harrison was the chief engineer who appointed me."

There is now and then a sigh of relief when the telephone suit is spoken of, when the thought comes up, that in a comparatively short time somebody will be declared winner, and there will be an end to pretense, claim and assumption on the part of the original and only, or the other original and only. "Which is the murderer and which is the victim," as the chap asked of the delineator of a "wax figger show." Artemus Ward once remarked that there are two things in this world for which we are never prepared; one of these is twins. The other he never told, but a spiritualistic friend has learned that it is the finding we are to have in the case of the United Swindle *vs.* the Bell Telephone Co.

Wandering back, mentally, to the City Hall, there is to be some change in our city plant, which is an Edison. The battery of dynamos now consists of two 300 light and two 400 light machines, a total capacity of 1,400 lights. This will be increased to two of 500, and two of 400, or a total of 1,800 lamps. A natural query is, "what are you going to do with the old ones?" Well. The city has just completed a tunnel out into the lake about 1,800 feet, which is connected to the north side water works. Through this underneath route a kind of duplexed conductor has been laid in the solid masonry, leading from the shore to the farther end, where they will terminate in a light house 75 feet high, and a motor for ringing a 1,000 pound bell in thick or heavy weather. One return wire (two conductors) and two outgoing wires with proper switches will handle all this at the shore station, and the lanterns, a combination of ten 50 c. p. lamps, may be lighted, or the little tea bell, as the river men call the monster, rung, separately or together at will. The other dynamo will be relegated to the west side water works, where it will do the lighting, and perhaps some light motor work. Then too, the new fire boat is to be equipped with a combined arc and incandescent system, with an apportionment of lights on tripods for illuminating at fires, and three lights on the vessel, while the interior will be lighted with glow lamps. At one or two fires we have had the benefit of an electric light in a dark alley, and it is a great help to the firemen.

CHICAGO, February 20, 1887.

ELECTRICAL NEWS AND NOTES.

THE ELECTRIC CLUB.

The meeting of the Electric Club of New York, February 3d, filled the club rooms at the Hotel Dam with the customary large number of gentlemen interested practically and commercially in electrical matters.

After the excellent dinner was disposed of, Mr. Henry Hine read a paper entitled "Electricity and Insurance." In the course of his forcible remarks Mr. Hine said:

"The insurance companies should not be blamed for their conservative course in the past, and when we consider the phenomenal development of electric lighting, its widespread use and the tremendous forces which are so freely handled in its generation and distribution, too much praise cannot be given the electric light companies that so little damage has been inflicted on life and property. To-day I believe that all the insurance associations, admit that the electric is as safe as other lights, and some go even farther and do not hesitate to say that it is much safer when properly installed. Now this is all that the electric light companies claim. We not only freely admit, but take pains to publish the fact that great danger would attend imperfect and careless equipment, but we emphatically assert that such work has not been the rule, and that as installed to-day by the reputable companies, an electric light system whether arc or incandescent, isolated or central station, continuous, pulsating or alternating current, contains fewer elements of danger than lighting by gas or oil."

The reading was followed by an interesting discussion.

The Electric Club, with its handsome rooms, hospitably open to electricians visiting the city, its monthly dinners and discussions, and its membership of active men in various fields of electrical work, has become a very useful and attractive organization.

STORAGE BATTERY LITIGATION.

Suit has been begun in the United States Circuit Court by the Brush Electric Company, of Cleveland, Ohio, against Charles D. P. Gibson, of New York city. The suit is founded on the claim of the Brush company that the Gibson storage battery is an infringement upon certain letters patent of the United States owned by that company. Subpœna to appear and answer is made returnable on the first Monday of March. The suit is brought on letters patent of the United States, No. 266,090, issued October 17th, 1882, No. 337,298 and No. 337,299, issued March 2d, 1886. This suit is said to be only the beginning of a general attack upon infringers of the Brush patents, and is likely soon to be followed by interesting developments.

THE TELEPHONE.

The arguments in the appealed telephone cases before the Supreme Court at Washington, were concluded February 8th. Their hearing occupied the time of the court for a fortnight. The judgment of the court will probably not be given for several months.

It is reported that the New York, New Haven and Hartford R. R. Co. has contracted for the introduction of the Phelps induction telegraph, for communication with moving trains, upon its road.

Italy.—Destruction of Telephonic Plant.—The director of the telephones in Genoa has issued a notice saying that the offices must be closed, the damages caused by the recent snow-storm amounting to more than £80,000.

LONG-DISTANCE TELEPHONY ABROAD.

The telephonic communication now existing between Paris and Brussels excites much interest. It is the first international line in Europe, and it is the longest yet attempted. An an example of long-distance telephony, it claims attention by reason of the difficulties which have been overcome. Special bronze wires were erected, and through these intercourse may be carried on with the greatest ease. The Brussels-Paris line is about 200 miles in length. That from Lille to Paris is 150 miles. Besides these two, there is a line from Paris to Reims, another from Rouen to Havre, another from Rouen to Elboeuf and Louviers, and some others of less importance.

A STATE ELECTRICAL LABORATORY FOR FRANCE.

The French government has decided to establish "a central laboratory of electricity," under the direction of the minister of posts and telegraphs. M. de Nerville has received the appointment of director of the new institution, although nothing has yet been decided as to the exact organization and functions of the establishment. It is, however, probable that the verification and calibration of electrical instruments will form the chief part of work undertaken, and it is hoped that a department for special research will also be included. A commission is to be appointed to determine these matters.

ELECTRIC LIGHT AND POWER.

Domestic.

In the *Electrical World*, Mr. T. C. Martin figures up that there is now invested in the electric light industries, of this country, on a cash basis, the total sum of $150,000,000.

The Ball Electric Light Co. has elected the following trustees: Messrs. Frederick Lovejoy, John C. Noyes, Chas. E. Ball, James H. Breslin, Robert Dunlap, William L. Brown, D. W. C. Wheeler, George W. Cotterill, Sol. Sayles, Wm. S. Hopkins, H. W. Spang. The following have been elected officers: President, Frederick Lovejoy; vice-president, John C. Noyes; secretary, G. P. Whitney; treasurer, Robt. Dunlap; electrician, Royal E. Ball: mechanical manager, Chas. E. Ball.

Salem, Ind., will be lighted by electricity. J. F. Persise, B. T. Race, L. O. Saltmash, and Charles May are interested.

Thomas Knowlson, West Troy, N. Y., will establish a new electric light plant.

The Lynn Gas Light Co., Lynn, Mass., contemplates establishing an electric light plant.

An electric plant will be established in Easton, Md. President, P. S. Reed.

The Electric Light Co., Asbury Park, N. J., contemplates establishing a plant at Red Bank.

West Grove, Pa., will be lighted by electricity. Address E. B. Gauthrop.

It is reported that Cairo, Ill., will be lighted by electricity. E. W. Halliday is interested.

Canastota, N. Y., will be lighted by electricity. Fred. C. Fiske, president.

Fayetteville, N. C., will be lighted by electricity. For further information address James D. McNeil or E. L. Pemberton.

Palmyra, N. Y., will be lighted by electricity. W. A. Powers is interested.

Mobile, Ala., is advertising for electric street lamps.

Rome, Ga., will have a new electric lighting plant. Mr. J. W. Rounsaville can give particulars.

The Kansas City Electric Light Co., Kansas City, Mo., will erect a complete plant, arc and incandescent system. J. S. Chick, president of the company, can give particulars.

The Concord Gas Light Co., Concord, N. H., will introduce electric lighting.

Digitized by Google

The Ann Arbor Thomson-Houston Electric Co., of Ann Arbor, Mich., has been incorporated, with a capital of $50,000, and Messrs. Wilbur F. Davidson, of Port Huron; E. J. Dickey, of Detroit, and A. L. Noble, of Ann Arbor, as incorporators.

The Wheeling Electric Co., Wheeling, W. Va., is enlarging its incandescent plant.

Lowenstein Bros., Memphis, Tenn., will put a 90 light arc plant from the Western Electric Co., in their new wholesale dry goods building.

The Western Electric Co. has received an order for an arc plant of 180 lights from the Lake Gas company, town of Lake, Ill.

Paola, Kan., has granted a franchise to the Sperry Electric Light, Motor and Car Brake Co., and a Sperry plant will be put in.

The Ottawa, Kan., Electric Light and Power Co. has contracted with the Heisler company of St. Louis, for a 150 light incandescent dynamo and complete outfit. The lights are of 30 c. p.

Treasurer E. I. Frost, of the St. Paul Gas Co., St. Paul, Minn., says the American system of electric lighting is giving the best of satisfaction, and that he expects to more than double his capacity this year. An additional 50 light machine and lamps were shipped recently to him by the American company.

The Brush Electric Light Co., New York, are busy erecting their new station on Elizabeth street. They are setting 10 tubular boilers with the Jarvis boiler setting and Sheffield grate bars. This company was the first local electric light company to be formed in the world.

The Western Electric Construction Co., of St. Louis, have successfully completed Edison central station plants in the towns of Topeka, Hutchinson and Abilene, Kansas. The Topeka station has a capacity for 5,000 lights; the Abilene, 4,500, and the Hutchinson, 1,900. The Topeka plant started with a load of 2,000 lights, and the Hutchinson, and Abilene with about 1,000 each.

The Holroyd Smith system of operating street cars by electricity, now in use successfully at Blackpool, England, is offered for introduction in this country.

The Sprague motor has been so successful in transmitting power over wires, in Boston, and running elevators, printing presses and other machines requiring from 1 to 20 h. p., as to create a demand for electric power beyond the capacity of the present arrangements. It is said a Sprague power station will soon be started at the north end of Boston for furnishing power alone.

The Van Depoele company has a contract for a large new electric road at Binghamton, N. Y., and is busy on the Montgomery, Ala., road. The Appleton, Wis., road is to be enlarged.

The Mount Adams and Eden Park street railroad company, Cincinnati, O., operating lines on Walnut Hill, have decided to make the Oak street line an electric road, and changes to accomplish that result will be made at once. It is understood that this is for an experiment, and that, should it succeed, electricity will be used largely on street railroad lines in that city.

Mr. E. H. Johnson, president of the Edison Electric Light Co., has had a set of cells from the Electrical Accumulator Co. installed in his house. Formerly the engine driving the dynamo was stopped at midnight, after which gas was employed. With the accumulators added to the plant the electric light is available at all times, much to the gratification and comfort of the owner.

The interior of the Washington monument is now lighted by the incandescent light of the U. S. Electric Lighting Co.

Foreign.

Austria.—There are seven distinct stations for the supply of electricity projected for Vienna. These are the following:

1. A central station at Neubad for running 15,000 glow lamps in the shops and dwelling houses of the inner town; contractor Herr Fischer. 2. A central station in Blutgasse, close to the St. Stefan's Cathedral, also with 15,000 glow lamps distributed in various newspaper offices, shops, some private houses, and the government printing offices; contractors, Messrs. Siemens & Halske. 3. A small central station close to the Union Hotel, where accumulators will be used, the number of lights not yet ascertained; contractor, Mr. de Calo. 4. Imperial Continental Gas Association, close to the new Burg Theatre, for 14,000 glow lamps, worked by steam engines and direct driven dynamos in conjunction with a series of accumulators; the light will be used in the two principal theatres, the Opera House, the Emperor's Palace, and the offices of the gas company; contractors the Gas Company. 5. A small central station in the Paniglasse, for a number of glow lamps distributed in the neighborhood; contractors, Messrs. B. Egger & Co. 6. A central station in the suburb Mariahilf, for 12,000 glow lamps; steam power, 1,000 h. p.; there will be 12 dynamos, each giving 480 amperes and 125 volts; contractors, Messrs. Kremenezky, Englander & Leistler. 7. A central station at the water works in Nussdorf; number of lamps not yet ascertained; here transformers on the Zipernowsky system will be used. The realization of these various projects is, however, to a certain extent, retarded by the action of the municipal council, who, in their jealousy of allowing the development of anything approaching a monopoly, go a long way towards making improvements of any kind impossible. The conditions to which electric light contractors are asked to submit are very onerous; for instance, the gas company are asked to pay a rental for the right of way for their street mains of 1 kr. (about $\frac{1}{5}$ of a cent) per annum for every yard of conductors, and for every service lead between mains and houses 1 fl. per annum. In addition, they are asked to hand over to the town 5 per cent. of their gross income from the sale of electricity. It is further proposed that, by giving a year's notice, the town can at any time compel the company to sell them the undertaking.

A warm debate took place in the Vienna town council on the 13th inst. on the question of granting a concession to the Imperial Continental Gas Association for a central station to light the Court theatres by electricity, when some very hard words were said of this and other English companies generally. The concession was nevertheless granted for 20 years by a majority of 51 to 15.

Belgium.—A company has acquired the concession for lighting the town of Contich at the following charges:—

For Installation (Incandescence).

1 to 5	lamps at	20 francs	per lamp.
6 to 25	"	18 "	"
26 to 50	"	16 "	"
51 to 100 and over	"	13 "	"

For Supply of Light (Incandescence).

4 centimes	per hour, per lamp of	8 to 10 candles.
7 "	"	16 to 20 "
12 "	"	40 to 50 "

Arc Lighting.

40 centimes	per hour, per lamp of	500 to 1,000 candles.
50 to 55 "	"	1,500 to 2,500 "

England.—The rate-payers of Penzance have given an opinion in favor of the electric light. The next question for them will be as to the manner in which they will carry out their desires. It is said to be probable that a suggestion will be made to the corporation that they should themselves become an electric light company, and undertake the duty of adequately illuminating the town, which has so long been doomed to semi-darkness. For an outlay of about £4,000 a double plant could be obtained, sufficient to light 60 lamps. Thirty of the lamps could be used for street lighting, and the remainder be let out for shops and public buildings.

Hungary.—The old fortress of Temesvar, in the south of Hungary, was one of the first towns that adopted the electric light. An installation of incandescent street lighting was started on the 30th November, 1884, with 731 Lane-Fox lamps, worked by Brush dynamos of 1,500 volts pressure. Some of the lamps are, *Industries* states, still in use, having lasted for 6,500 hours, and it is satisfactory to note that, notwithstanding the high pressure employed, there was, during the whole time, not a single accident, nor any serious breakdown. Encouraged by this success, the corporation of Temesvar are now considering a further application of electricity, for the purpose of working their tramways by electric motors. The project is to run street cars fitted with accumulators, which would be charged at the electric light station during the day, and in this way the generating plant would be kept more fully employed, and thus made to yield an additional profit.

Russia.—The municipal council of St. Petersburg has, after long discussion, decided in favor of continuing the electric lighting of the Novsky and of the Grande Moskaia. The contract has been let to the firm of Siemens & Halske, who have received a concession for twelve years for the electric lighting of private houses, and also the right of establishing four electric stations at a rent of £80 each. In consideration of these privileges they charge for the public lighting of the two streets above mentioned 17 cop. (about 4d.) per hour per light.

Scotland.—The Glasgow Tramways Co. desires powers from Parliament to work its road with electric motors.

Spain.—A company called the "Electro-Dynamic Association of Carsi, Mari & Co.," has been formed in Valencia, with the object of utilizing water power to be obtained at the Falls of Chulilla on the river Turia, situated at a distance of 56 kilometres from Valencia. It is proposed to erect the generating machines at the village of Torzuilla, whither the water power will be conducted by a subterranean canal of 1,762 metres and an open one of 741 metres. It will be also necessary to construct dams, sluices, flood gates, accessory canals, turbines, &c. Observations have shown that the power obtainable varies from a minimum of 2,000 h. p. in summer to a maximum of 3,500 in winter. The experiments lately effected by Mons. Fontaine with Gramme machines, resulting in the transmission of an industrial return equal to 52 per cent. of the original force, have encouraged the company to rely upon an effective working power of at least 1,000 h.p., which will be used for public and private electric lighting, and as motive power for various descriptions of machinery.

Digitized by Google

NEW INCORPORATIONS.

The Electric Light and Power Co., of St. Louis, recently incorporated under the laws of Illinois with a capital of $1,000,000, are developing an electric storage battery system with a view of supplying electric energy for domestic and commercial lighting, and for all purposes for which power is used. The system, invented by Sylvanus L. Trippe, is said to have been tested on several occasions to the satisfaction of the incorporators, who are D. P. Slattery, J. L. Huse, Edwin S. Chester, James F. Ewing, and the inventor. Practical applications will be made in the moving of street cars in St. Louis at an early day, it is said.

The Hartford Light and Power Co., Hartford, Conn. Capital stock, $10,000. David Henry, and others, incorporators.

The Lake View Electric Light Co., Lake View (P. O. Chicago), Ill. Capital stock, $100,000. William Vogel, and others, incorporators.

The American Illuminating Company, Mt. Vernon, N. Y. John Dawson, and others, incorporators.

The Western Electric Light and Power Co., Toledo, Ohio. Capital stock, $200,000. John T. Kinnler, and others, incorporators.

The Empire Safety Light, Heat and Power Co.; the Manhattan Safety Light, Heat and Power Co., and the National Safety Light, Heat and Power Co., of New York city, N. Y. Capital stock, $5,000 each. Caleb W. Jackson, Pittsburg, Pa., and others, incorporators.

The Latrobe Electric Light Co., of Latrobe, Pa. Capital stock, $12,000. Treasurer, Joseph C. Head, Latrobe.

The Safety Electric Light and Power Co., New York city, N. Y. Capital stock, $250,000. Herman H. Westinghouse, and others, incorporators.

The Electric Light Construction Co., Albany, N. Y. Capital stock, $50,000. Wm. Headlam, and others, incorporators.

The Mutual Electric Light Company, Chicago, Ill. Capital stock, $100,000. James E. Purnell, and others, incorporators.

The Moberly Electric Light and Power Co., Moberly, Mo. Capital stock, $50,000. Henry T. Fort, and others, incorporators.

The Ries Electric Railway Manufacturing Co., Portland, capital stock, $1,000,000, has been incorporated. President, Robt. F. Straine, Sr., Boston, Mass.

The Globe Electric Light and Power Co., of Minneapolis, Minn., for the manufacture of electrical machinery and supplies. Incorporators are: B. F. Hanscom, J. Collicott, W. S. Laton, J. A. and F. N. Dunsmoor, R. S. McCurdy, C. H. Hunter, A. W. Armitage, J. Van der Horck, and W. Hallowell. Capital $500,000.

The Railway Electric Car Lighting Co. of Chicago. Capital stock, $100,000. J. J. Veeder, and others.

The Seaweed Carbon Co. has been incorporated at Portland, Me., with a capital of $200,000. It is composed of Massachusetts men, with Edgar Shaw, of Lynn, at the head, and will develop the new inventions of Mr. Shaw, for making carbon for electrical purposes out of the common seaweed stuff of the sea.

MANUFACTURING AND TRADE NOTES.

The Edison machine works have changed their salesroom from 121 Chambers street to 19 Dey street, New York.

PERSONAL MENTION.

It is understood that the Hon. Hiram Sibley is to enlarge his munificence to Cornell University by a further gift of a quarter of a million dollars. The money is to be used for improving and extending the Sibley College of Mechanic Arts. A large building is to be constructed to the east of the present structure early in the spring, and provision made for the instruction of many additional students in technical and mechanic arts.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From January 18 to February 8th, 1887 (inclusive).

Alarms and Signals:—*Automatic Heat Indicator and Distant Alarm*, W. Gee, 356,360. *Electrical Call Box*, G. S. Nickum, 356,418, January 18. *Electric Clock Alarm*, M. M. Smith and F. P. Jones, 356,605, January 25. *Electrical Call System*, J. D. Peachey, 356,850. *Electrical Method of Detecting Water Overflows*, L. Well, 357,056. *Electric Signal for Engines*, J. C. Ricketson, 356,792. *Alarm for the Protection of Graves*, W. H. Farnham and C. B. Askew, 356,756, February 1. *Electrical Burglar Alarm*, G. Schleicher, 357,416. *Thermostat*, J. L. Campbell, 357,463, February 8.

Conductors, Insulators, Supports and Systems:—*Underground Conduit for Electrical Conductors*, J. F. Munsie, 356,151. *Conduit System for Electric Conductors*, same, 356,152. *Electric Wire or Cable Distributing System*, same, 356,153. *Insulating Telegraph Cables*, W. R. Patterson, 356,156. *Manufacture of Telegraph Cables*, same, 356,206. *Method of Insulating Electric Conductors*, same, 356,207, January 18. *Insulated Ball-Joint*, J. A. Bunnell, 356,614, January 25. *Insulating Underground Electric Conductors*, D. Brooks, 356,981, February 1. *Electrical Distribution*, W. B. Harvey, 357,280, February 8.

Dynamos and Motors:—*Dynamo-Electric Machine*, S. H. Short, 356,667, January 25. *Commutator-Adjuster for Dynamo-Electric Machines*, C. L. Buckingham, 357,115. *Armature for Dynamo-Electric Machines*, E. Thomson, 356,902, February 1. *Commutator for Dynamo-Electric Machines*, G. Westinghouse, Jr., and A. Schmid, 357,295, February 8. *Electric Motor*, P. Diehl, 356,576, January 25; W. W. Griscom, 356,834; E. J. Houston, 356,878, February 1. *Electro-Magnetic Motor*, W. H. Darling and L. Bock, Jr., 357,374, February 8.

Galvanic Batteries:—*Primary Voltaic Battery*, J. E. Pearce, 356,261, January 18. *Galvanic Cell*, N. W. Perry, 356,727, January 25. *Galvanic Battery*, S. A. Chase, 357,550, February 8.

Lamps and Appurtenances:—*Electric Arc Lamp*, A. Harding, 356,282, January 18; E. Thomson, 356,903; H. L. Pyle, 356,786 and 356,788, February 1. *Incandescent Electric Lamp*, W. Holzer, 356,199, January 18. *Dash-Pot for Electric Arc Lights*, C. E. Scribner, 356,211, January 18. *Supporting Frame for Electric Lamps*, H. H. Fairbanks and W. H. Coughlin, 356,580, January 25. *Terminal for Incandescent Lamps*, M. M. M. Slattery, 356,795. *Apparatus for Manufacturing Carbons*, J. T. Lister, 356,879, February 1. *Switch and Holder for Incandescent Electric Lamps*, W. Hoekhausen, 357,385, February 8.

Miscellaneous:—*Electrical Elevator*, N. P. Otis, 356,496. *Lightning Rod*, C. H. Grimes, 356,531. *Electric Cut-Out*, J. Fuchs, 356,632. *Electric Valve*, W. S. Johnson, re-issue 10,802, January 25. *Automatic Electrical Signal Coupler*, J. S. Copers, 357,165. *Process of Purifying Gas-Carbon*, F. H. Snyder, 357,108. *Automatic Electric Cut-Off for Water Pipes*, L. Well, 357,055. *Lightning Protector for Electrical Conductor*, J. H. Vail, 357,050. *Electrical Weighing Scale*, W. M. Hunt, 356,940. *Fire Extinguishing Apparatus*, W. Harkness, 356,875. *Device for Displaying Advertising Cards*, J. Stonitsch and W. F. Sweet, 356,805. *Contact Piece for Electrical Apparatus*, M. M. M. Slattery, 356,796, February 1. *Life Detecting and Preserving Apparatus*, W. H. Farnham and C. B. Askew, 357,190. *Electric Cut-Out*, O. B. Shallenberger, 357,293. *Instrument for Transmitting Audible Time-Signals*, J. R. Etter, 357,310. *Electrical Fare-Box*, W. A. Crowdus, 357,372, February 8.

Railways and Appliances:—*Electric Locomotive*, H. Erhardt, 356,579, January 25. *Electrical Interlocking Mechanism for Switches and Signals*, G. Westinghouse, Jr., 357,109. *Method of Operating Electric Brakes*, E. E. Ries, 356,964. *Circuit Closing Apparatus for Electric Brakes and Other Devices*, same, 356,963, February 1. *Electric Railway Signaling*, G. Westinghouse, Jr., 357,296. *Electro-Magnetic Attraction Device for Cars*, J. B. Atwater, 357,516, February 8.

Secondary Batteries:—*Electric Accumulator*, C. B. De Montaud, 356,390, January 18.

Telegraphs:—*Autographic Telegraph*, J. H. Robertson, 357,038 and 357,039, February 1.

Telephones, Systems and Apparatus:—*Telephone*, E. H. Johnson, 356,688 and 356,689, January 25. *Telephone Transmitter*, W. C. Barney, 357,359; F. Blake, 357,452, February 8. *Telephone Receiver*, E. T. Gilliland, 356,197, January 18; W. C. Barney, 357,360, February 8. *Krotophone Receiver*, F. C. Watkins, 357,054, February 1. *Mechanical Telephone*, G. W. Lord, 356,594, January 25. *Telephone System*, A. M. A. Beale, 356,300, January 18; J. O. Stockwell, 357,134, February 1. *Test Circuit for Multiple Switch-Board System*, C. E. Scribner, 356,425. *Multiple Switch-Board Test Circuit*, same, 356,426. *Factory Telephone Exchange*, same, 356,427, January 18. *Automatic Telephone Switch*, F. C. Watkins, 357,051. *Telephone Signal*, same, 357,052. *Telephone Hook*, same, 357,053. *Multiple Switch-Board System of Telephone Exchanges*, E. P. Warner, 356,859, February 1. *Telephone Support*, S. Rosenblatt, 357,337. *Spring-Jack Switch*, C. E. Scribner, 357,538. *Metallic Circuit for Multiple Switch-Boards*, J. A. Seely, 357,539. *Local Battery Circuit for Multiple Switch-Board Systems*, same, 357,540, February 8.

OKONITE

TRADE MARK.

CHAS. A. CHEEVER, Pres. WILLARD L. CANDEE, Treas.

The Okonite Company,

MANUFACTURERS OF

Underground, Aerial and Submarine

Insulated Wires and Cables,

No. 13 Park Row, New York.

MITCHELL, VANCE & CO.,

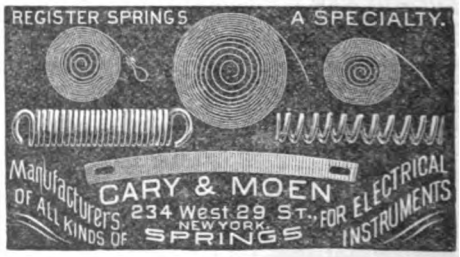
GAS FIXTURE MANUFACTURERS,

Have added a department for the Manufacture of Electroliers and other fixtures adaptable to any system of Incandescent Electric Lighting, also Combination Fixtures for both Gas and Electric Light.

Estimates and designs furnished upon application.

836 and 838 BROADWAY,

NEW YORK.



WANTED.

A gentleman well versed in Electricity desires a situation as Assistant Electrician.

Address, LAWRENCE ZIMMERMANN,

326 Manhattan Ave., Brooklyn, N. Y.

THE ELECTRICIAN
AND
ELECTRICAL ENGINEER.

Conducted by F. L. POPE. G. M. PHELPS, JR., Associate Editor.

PUBLISHED MONTHLY BY

THE ELECTRICAL PUBLISHING CO.,

115 Nassau Street, New York city.

European Agent, F. H. WEBB, 4, The Sanctuary, Westminster London, S.W., Eng

TERMS OF SUBSCRIPTION.

United States and Canada,	per annum,	$3.00
Four or more Copies, in Clubs (each)	"	2.50
One Copy, Four Months,		1.00
Great Britain and other Foreign Countries within the Postal Union	"	4.00
Single Copies,		.25

[*Entered at the Post Office at New York, N. Y., as second class mail matter.*]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

NEW YORK, APRIL, 1887.

ANNOUNCEMENT TO SUBSCRIBERS.

WE are pleased to recognize the fact that a principal source of the growth of our subscription list is the favorable commendation of the ELECTRICIAN AND ELECTRICAL ENGINEER by those who are already subscribers, to their friends and acquaintances

We shall continue our endeavors to deserve your appreciation and good-will, by keeping up, and if possible improving the quality of our paper. To any of our present readers who may find it in their way to increase our list, we offer rates for 1887 as follows:

For your own subscription	and	1	new name	.....	$5	00
"	"	"	"	2	"	.....	7	00
"	"	"	"	3	"	.....	9	00
"	"	"	"	4	"	.....	10	00

This offer will hold good until April 1st.

The *Telegraphic Journal and Electrical Review*, London, will be supplied for one year in conjunction with the ELECTRICIAN AND ELECTRICAL ENGINEER for the additional sum of $4.00 with any subscription.

In addition to the usual methods prescribed for making remittances, money orders issued by the American, United States or Wells Fargo express companies will be found safe, cheap, and convenient.

Very respectfully yours,

ELECTRICAL PUBLISHING CO.,
115 Nassau St., New York.

SPECIAL ANNOUNCEMENT.

BY arrangement with the *Electrical World*, New York, we are able to make the attractive offer of that valuable and enterprising weekly journal in conjunction with the ELECTRICIAN AND ELECTRICAL ENGINEER for one year for $5.00 to new subscribers. To our present subscribers we will supply the *Electrical World* one year for $2.50.

PATENT OFFICE METHODS.

CONGRESS adjourned without taking up the annual attack upon the patent system of the country, which was initiated early in the session. It may safely be assumed that no serious danger to the continuance of a system which has, on the whole, worked so well for the development of industry is to be apprehended from the recurring efforts of those who would abolish all proprietorship in invention. The good sense, not to say justice, of the country is clearly on the side of the inventors.

Much, however, can be done to increase the usefulness and benefit of the patent system, to both inventors and the public. The desirability of better methods in the patent office, and of improvement in the average character and qualifications of patent solicitors, is generally recognized by all whose interests are connected with property in patents, and is attracting some attention in the public press.

Two evils are very noticeable in the present working of the patent office; namely, the great delay incurred in getting applications through to final action, and the multitudinous issue of patents on frivolous or useless devices, often mere expedients of the most obvious character, wholly unworthy of the name of inventions. The last named evil is unquestionably in large part the cause of the first, for in this way the facilities of the patent office are burdened beyond its capacity to dispatch business. There has been a manifest improvement during the past year in overtaking arrears of work, as shown in the annual report of the commissioner, but the situation is still very far from being satisfactory. The office is apparently doing its best, but under very discouraging conditions. Of the patents issued, to say nothing of the applications examined and rejected, it is safe to say that the interests of inventors and the public would be better served if more than one-half the alleged "useful inventions" had never reached the patent office. That they do reach the office, in applications persistently pressed till some sort of a patent is obtained, is largely due, to the multiplication of a class of solicitors whose methods resemble those of too many "claim" and "pension agents" in taking cases on speculation; "no patent no pay." Under the persistant pressure of such solicitors the practice of the patent office has tended toward a loose interpretation of the terms "useful" and "invention," till now they cover, if not a multitude of sins, a multitude of absurdities on the one hand and frivolities on the other. Among the latter are the innumerable cases in which the most ordinary mechanical skill or judgment is dignified by the name of invention. In reference to this class of patents, it must not be overlooked that the practice of the office in allowing them at all, often compels a meritorious inventor or

Digitized by Google

manufacturer working under established patents, to protect himself by making applications for patents upon many comparatively trifling features of machinery or processes—such as an ordinary workman would be sure to accomplish as a matter of course, and think nothing of it—lest it occur to somebody else to get patents therefor, and attempt to levy tribute upon all users.

In the New York *Evening Post* of March 25th, patent procedure is well discussed in a letter from "W. P. B." The writer directs attention to the desirability of some prescribed qualifications for admission to practice before the patent office. So long as the office receives business at the hands of anybody who chooses to call himself a patent solicitor, many meritorious inventions will be so badly presented as to cause great delay and an unreasonable amount of work on the part of the office; or as to be rushed through to the issue of valueless patents; and the number of trifling or useless devices patented will continue to increase in an accelerating ratio.

We quite agree with "W. P. B." that some prescribed qualification for solicitors is much needed, but hardly follow him in proposing the restriction of practice before the patent office to members of the bar. That a competent knowledge of the legal principles underlying the patent system is a necessary qualification will hardly be denied; but legal knowledge and experience, however wide and varied, can hardly take the place of the acquaintance with physics and the mechanic arts required on the part of a capable patent solicitor. It will probably be conceded by all who have had experience in invention or in the ownership of patent rights that a qualification for solicitors, based upon an adequate knowledge of fundamental patent law and of the arts and sciences, not omitting a reasonable familiarity with the use of language, would accomplish much to improve the working of the patent system. The only losers would be the incompetent and speculative solicitors who now burden the office with unnecessary work, and flood the country with worthless patents.

A WIDE-SPREAD interest in the subject of electrical distribution by secondary generators, was well attested by the addresses and discussion at the meeting of the American Institute of Electrical Engineers, March 15th. The assignment beforehand of "distribution by secondary generators" as the topic for the evening, elicited the attendance of a number of gentlemen well qualified by study or experience to elucidate and discuss it. Nothing can better serve to bring out the actual merit of new methods or systems than such gatherings of investigators and workers for their discussion. It is well for the usefulness of the Institute that its membership includes so many practical as well as theoretical electricians. The report of the meeting, printed elsewhere, will be read with interest by absent members of the institute, and by all our readers whose studies or pursuits bring them into any relation to the subject of the distribution of electricity. So rapid has been the recent development of successful methods of using electricity for light and power, and so accustomed have electricians already become to the situation, that it seems almost a platitude to say that electricity will at no distant day be supplied from house to house, for a variety of uses, much as water now is. Obviously the chief problem of the electrical engineer, at present, is, how best to transport and deliver electricity.

THE quarterly report of the Western Union Telegraph Company exhibits the continued decline of the net revenues of that company since 1883. For the year ending June 30, 1886, the net revenues were $3,919,855.13. In the president's report of March 9th, the net revenues for the quarter ending December 31, 1886, are given as $991,018—and the partly estimated revenues for the succeeding quarter as $750,000, or at the rate of $3,000,000 annually. This is less than the revenues of the company for any year since 1874. Although dividends are suspended, Western Union shares are maintained at above 75. There is a widespread impression that a consummation of the much talked of deal in Baltimore and Ohio Railroad stock will involve a closing out of the Baltimore and Ohio Telegraph business to the Western Union Company. Meantime President Bates of the Baltimore and Ohio Telegraph Company gives to the press a rose-colored account of the financial success of that company. (See page 165). Whether competition continue, or consolidation ensue, is of little moment to the general public, so that it get cheap telegraphing—but not too cheap to be efficient and trustworthy.

THE West, not to be behind the rest of the world, is keeping up its record by taking a leading part in developing electric railways. We print elsewhere a description of the electric street railway in Denver, furnished us by the United States Electric Company of that city. The system used at Denver—the joint production of Mr. Sidney H. Short, formerly Professor of Physics in the University of Colorado, and Mr. John W. Nesmith, President of the Colorado Iron Works—presents many points of interest to electrical engineers and the public. Its practical success seems to have been demonstrated by public use at Denver for a considerable period of time. Our San Francisco correspondent states that this system is to be tried on the electric railway laid out for that city.

We quite agree with our Denver friends that the comparison between their series system and a multiple arc system—as shown in the article—is somewhat unfair to the advocates of the latter. Certainly no electrical engineer would undertake to run a multiple arc system with conductors of the size employed at Denver. The disparity, shown in the comparison between the two systems in loss of energy in the conductors, would very rapidly diminish with increase in their size.

THE course of the Westinghouse Electric Company in promptly bringing suit upon the Gaulard & Gibbs' patent against the first discoverable infringer, is to be commended. The patent was issued in October last, and, as noticed in our news columns, a suit for infringement was brought March 15th against the Sun Electric Company. There is a directness about this procedure in striking contrast to the too prevalent practice of letting supposed infringers of important patents run on for years, till they have built up a business, and to the still worse practice of attacking them through the press. The interests of all directly concerned in the scope and validity of a patent, as well as of the public, are best served by prompt appeal to the courts.

ARTICLES.

THE STORY OF THE WORD "TELEPHONE."

BY THOMAS D. LOCKWOOD.

In a little book which I perpetrated in the year 1882, there was a chapter entitled "Facts and Figures about the Speaking Telephone." I made the rash statement in the opening paragraph of that chapter, that "The first record of a sound transmitting instrument in connection with which the word 'telephone' occurs, is *believed* to be the English patent of Sir Charles Wheatstone, No. 2,462 Oct. 10, 1860." This statement was strictly true. Such was at that time my belief.

The book in question was reviewed by the British *Telegraphic Journal and Electrical Review* and the above statement was commented upon as follows:

"We fancy the use of the word 'telephone' as a sound transmitter dates considerably farther back than 1860. Indeed, some of our readers may remember the well-known 'telephonic concerts' of Sir Charles (then professor) Wheatstone, given at the now defunct Polytechnic Institution very many years back, in which musical sounds were transmitted a considerable distance through wooden rods."

This comment, together with a consideration of the numerous and frequent absurd statements made by zealous advocates of the multitudinous claimants to the inventorship of the speaking telephone, determined me to find out what was discoverable in the matter, and to bring together in the pages of this magazine the result of my researches.

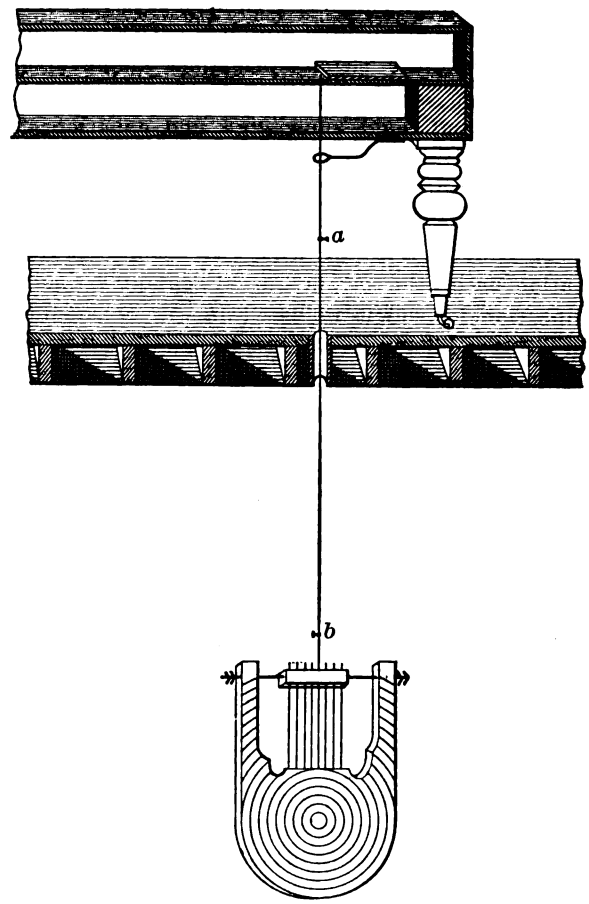
How frequently we hear, that "it is simply impossible that Professor Bell intended to patent or describe the speaking telephone in his 1876 patent; if he had he would have entitled it "telephone," whereas, he simply called it "telegraphy." Then on the other hand, we are gravely told that "Professor Bell was well aware before his invention, patented March 7th, 1876, that speaking telephones were well known to every one, or he wouldn't have referred to them by that name in a prior application for patent in harmonic telegraphy." Of course the wish with these advocates is very nearly related to the thought. It is, however, perfectly obvious to all who take thought in such matters, that the mere name of any invention is an immateriality; in this case, glaringly so; for the name is evidently applied to its present use simply for convenience; its very etymology indicating the true meaning; viz, "sound from afar,"—and of course it is equally easy to see that sound is not restricted to speech. With reference to the inference that some wish to draw from the circumstance that Professor Bell's patent is entitled "An Improvement in Telegraphy", it is only, I think, necessary to point out that the term "telegraphy" had from usage grown to be generic; and it was equally as reasonable to apply it to a speaking telegraph, as it was to the strokes of a sounder, or the visual indications of a Cooke and Wheatstone needle, or a Bright's bell instrument, none of which made a written or graphic record of their signals.

I will now give an abstract of the information which I have accumulated on this head.

Prof. Wheatstone, at quite an early period of the present century, was a persistent and energetic experimenter in the transmission of sound through solid bodies, and in 1821 succeeded in transmitting music "with all the varieties of tune, audibility and all the combinations of harmony unimpaired." He exhibited what he called "The Enchanted Lyre," and so perfect was the illusion in this instance, from the intense vibratory state of the reciprocating instrument, that it was universally imagined to be one of the highest efforts of ingenuity in musical mechanism. As a matter of fact the mechanism was of the simplest character, comprising only an ordinary lyre of eight strings, suspended by a wire extending through the floor from the sounding board of a pianoforte in a room above. The accompanying figure shows the arrangement.

These researches are recorded in the *Literary Gazette*, 1821; Ackerman's *Repository* of the same year; in a scientific paper written by Wheatstone himself for Thomson's Annals of Philosophy, 1823; vol. vi, pp. 81-90; and in a paper written also by Wheatstone for the Journal of the Royal Institution, 1831, vol. 2. The last paper records among other things, the much repeated observations of Robert Hooke, on communicating through a distended wire; and concludes with these remarkable words:—

"The transmission to distant places, and the multiplication of musical performances are objects of far less importance than the conveyance of the articulation of speech. The almost hopeless difficulty of communicating sounds produced in air with sufficient intensity to solid bodies, might induce us to despair of further success; but could articulations similar to those enounced by the human organs of speech be produced immediately in solid bodies, their transmission might be effected with any required degree of intensity. Some recent investigations lead us to hope that we are not far from effecting these desiderata; and if all the articulations were once thus obtained, the construction of a machine for the arrangement of them into syllables, words, and sentences, would demand no knowledge beyond that we already possess."



It is to be noticed that the idea that articulations might be transmitted and reproduced *by the agency of electricity* does not seem to have occurred to Prof. Wheatstone.

Before dismissing Professor Wheatstone's own papers, it will be interesting to note that in October, 1837, he compiled an article for the London and Westminster *Review*, in which he gave an account of the several attempts which had up to that time been made to imitate the articulations of the human voice by mechanical means; and that this article concludes with the paragraph "There are no doubt a great many difficulties yet to be contended with, before we can succeed in perfectly imitating the articulations of speech; but the partial success of the attempts of which

Digitized by Google

we have laid an account before our readers, ought to encourage further trials. It is not too much to say in the words of Sir David Brewster, 'We have no doubt that before another century is completed, a talking and a singing machine will be numbered among the conquests of science.'"

It is also interesting to note *en passant* that Professor Wheatstone devised a mechanical instrument (which he describes in the *Quarterly Journal of Science* for 1827) for rendering audible the weakest sounds, to which he gave the name of *microphone*.

I have been somewhat disappointed to find that in these papers Wheatstone himself does not employ the word "telephone," although there is reason to believe that he was in the habit of referring to his appliances for transmitting sound by that name. In a work entitled "Posts and Telegraphs, Past and Present," published in 1878, I find the following amusing anecdote of Sir Charles Wheatstone's acoustic performances, given by a Mr. William Chappell: "An eminent foreign performer on the violincello came to England, bringing a letter of introduction to Wheatstone. He left the letter at the house, and made an appointment to call at a particular hour on the following day. Wheatstone was at home to receive him, and thinking to surprise and amuse his visitor, hung a violincello on the wall of the passage, having a rod behind it to connect it with another, which was to be played from within when he entered the hall. The guest turned in every direction to find whence the sounds came, and at last approaching the violincello hanging on the wall, and having satisfied himself that they proceeded from it, although there was neither hand nor bow to play upon it, he rushed out of the house in affright, and would never enter it again."

In Timbs's Year Book of Facts in Science and Art, for 1845, is found on page 55, this item:

"THE TELEPHONE."

"Captain John Taylor has invented this powerful instrumsnt for conveying signals during foggy weather by sounds produced by means of compressed air forced through trumpets; audible at six miles distance. The four notes are played by opening the valves of the recipient, and the intensity of sound is proportioned to the compression of the internal air. The small sized *telephone* instrument which is portable, was tried on the river and the signal notes were distinctly heard, four miles off. The instrument is engraved in a late number of the *Illustrated London News*."

The next published instance of the use of the word "telephone" occurs in the same journal—Timbs's Year Book of Facts; but for the year 1854.

It is entitled "*New Telephone*," and reads:—"A very curious system of telephony *for the transmission of language* at great distances by means of musical sounds has been invented by M. Sudre, at Paris. The plan consists in making use of three notes placed at given intervals; and which when combined or repeated according to certain rules, are capable of rendering the most complicated sentences. Thus one of the company writes a few lines, and on M. Sudre reading them, he strikes his three notes alternately according to his method, when a third person without any previous knowledge of the writing repeats the words merely from hearing the notes. The system has been, it is understood, tried on a very extensive scale to test its applicability to naval and military purposes, and it is stated fully to justify the high enconiums the French Institute and other scientific bodies have bestowed on it."

At this epoch we find that Wheatstone once more crops up.

Referring again to the little book—"Posts and Telegraphs" by Tegg; London, 1878, page 290 I find the following:—

"On the 10th of May, 1855, an exhibition took place before Her Majesty the Queen, at the Polytechnic Institution, of which the only account that has been reproduced is that given by Mr. C. K. Salaman, in a letter to the 'Choir':—

"1. Lecture by J. H. Pepper, Esq., on Professor Wheatstone's experiments on the transmission of musical sounds to distant places, illustrated by a *telephone* concert, in which sounds of various instruments pass inaudible through an intermediate hall, and are reproduced in the lecture room, unchanged in their qualities and intensities."

The sounds produced in a lower room were carried through a wooden rod to the lecture room.

Prof. J. H. Pepper describes this occurrence in his "Cyclopedic Science Simplified," London, 1869.

In 1871, in a course of lectures on sound, Professor Tyndall repeated this illustration; and the repetition is recorded in the Journal of the Society of Arts, vol. 19.

We now arrive at Wheatstone's British patent, No. 2,462, of 1860, in which he claims among other inventions—

"The employment of musical pipes or free tongues acted upon by wind in the construction of *telephones*, in which the alternation of long and short sounds are grouped in a similar manner to the long and short lines in the alphabet of a Morse's telegraph; or in which two sounds are made to succeed in the order of the alternate motions which constitute the alphabet of a single needle telegraph."

The next example is the telephone of Philipp Reis:—"I give to my instrument the name telephone," *vide* Jahresbericht of the Physical Society, Frankfort, 1860–1861.

The name was then applied almost exclusively to this instrument from this time until the advent of the speaking telephone.

In February, 1875, Mr. Alexander Graham Bell used the word to indicate a vibrating receiver in a system of harmonic telegraphy, and describes it in these words "For instance, with a series of transmitters I can place at the receiving end of the line a telephone from the rod of which silk threads may lead to a series of bodies such as tuning forks capable of definite vibration, each one of these bodies having a rate of vibration corresponding to one, and one only, of the transmitters. In case two or more different sets of impulses be transmitted simultaneously to the telephone, each will affect that one alone of the tuning forks whose vibrations are synchronous with the impulses. The same effect could be produced by resonators of different pitches placed under the rod of the telephone."

And during the years 1875–1878 Elisha Gray applied the term "telephone" to his entire harmonic system—*vide* U. S. Patent No. 175,971, April 11, 1876, Telephonic Telegraphs; "A New and Practical Application of the Telephone," by Elisha Gray—Journal of the American Electrical Society, 1877. "The Telephone, the Microphone and the Phonograph," Du Moncel, Paris, 1878, "Electricity and the Electric Telegraph," Prescott, 1878, pp. 868–880; and the Gray and Bell correspondence in February, 1877, (Dowd Case, vol. 1, pp. 146–147), in which Mr. Gray says "I gave a lecture in McCormick Hall, this city (Chicago), Tuesday evening, 27th inst., on the telephone, as *I* have developed it. I also connect with Milwaukee, and have tunes and telegraphing done from there."

The term "telephone" seems to have been applied by Mr. Bell in his paper before the American Academy of Arts and Sciences, May 10, 1876, to harmonic and speech receivers and transmitters indiscriminately; but referring once more to the Gray and Bell correspondence we find that Mr. Bell has, under date of March 2d, 1877, reached a point where "telephone" for him has but one meaning. He says, "I have not generally alluded to your name in connection with the invention of the electric 'telephone,' for we seem to attach different significations to the word. I apply the term only to an apparatus for transmitting the voice (which meaning is strictly in accordance with the derivation of the word), whereas you seem to use the term as expressive of any apparatus for the transmission of musical tones by the electric current."

Thus we see that the word "telephone" is not a new

Digitized by Google

word, but that it has in the past been used in a variety of ways.

It seems to me, therefore, that the definition given to the word in Knight's American Mechanical Dictionary is a fair and pertinent one. This is "TELEPHONE, an instrument for conveying signals by sound. It may consist of a steam whistle, a fog trumpet, or other audible alarm. The term, until lately, has been particularly applied to a signal adapted for nautical or railroad use, in which a body of compressed air is released from a narrow orifice, and divided upon a sharp edge in the manner of a steam whistle. The term is now acquiring a different signification."

However, since the Centennial exhibition of 1876, the application of the term to an apparatus for the transmission and reproduction of speech has become well nigh universal; and every other meaning seems to be totally superseded.

I have thought it worth while, therefore, to make a compact record of the instances of its use otherwise which I have been able to find.

THE ELECTRIC LIGHTHOUSES OF MACQUARIE AND OF TINO.*

BY JOHN HOPKINSON, M.A., D.SC., F.R.S., M. INST. C. E.

THE subject of the use of the electric light in lighthouses was fully discussed at the Institution in 1879, when papers by Sir James Douglass, M. Inst. C. E., and by Mr. James T. Chance, Assoc. Inst. C. E., were read.[1]

The subject has been further elaborately examined by Mr. E. Allard,[2] and more recently in practical experiments made at the South Foreland, exhaustively reported on by a committee of the Trinity House.[3] The justification of the present communication is that, at the lighthouses of Macquarie and of Tino, the optical apparatus is on a larger scale than has hitherto been used for the electric arc in lighthouses, and presents certain novel features in the details of construction. Further, as regards the electrical apparatus, tests were made upon the machinery for Macquarie when it was in the hands of Messrs. Chance Brothers and Co., which still possess some value, although five years old; and, in the case of Tino, the machines are practically worked together in a manner not previously used otherwise than by way of experiment.

In the case of both lighthouses, Messrs. Chance Brothers and Co., of Birmingham, entered into a contract for the supply of all the apparatus required, including engines, machines, conductors, lamps, optical apparatus, and lanterns; and Sir James Douglass, engineer-in-chief of the Trinity House, acted as inspecting engineer to the respective colonial and foreign governments.

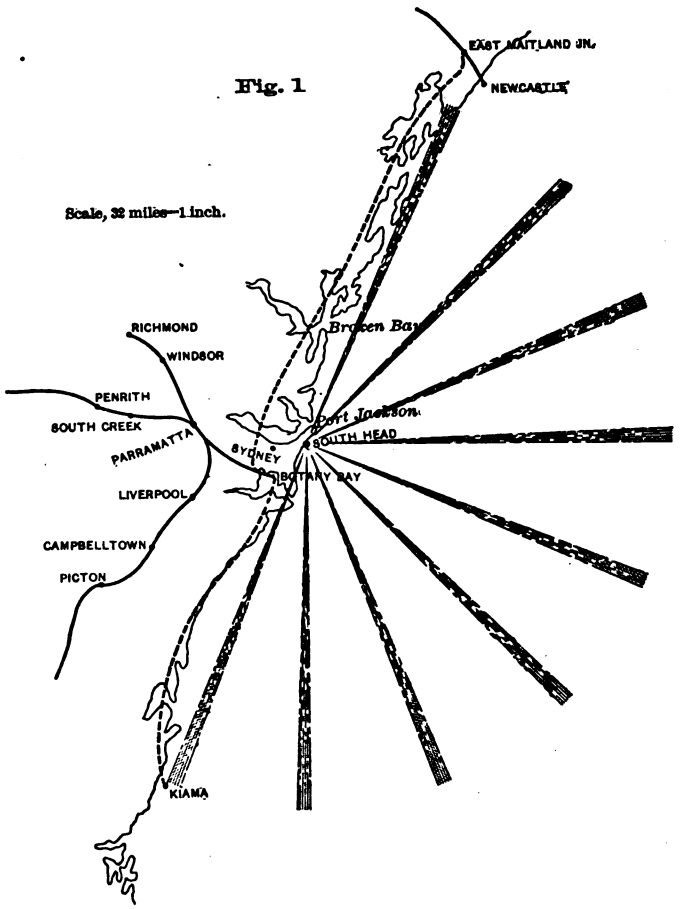
As these two lighthouses present many features in common, it may be most convenient to give a full description of the earlier lighthouse, and then limit the description of Tino to those points in which it differs from Macquarie.

MACQUARIE.

This lighthouse is situated on South Head, near Sydney, the precise position being shown in a copy from the chart, plate 9, figure 1. A lighthouse was first placed at this important landfall in 1817. The focal plane is 346 feet above the sea, and the distance of the sea horizon is, therefore, 21.6 nautical miles, and the range about 27 nautical miles for an observer 15 feet above the sea.

Optical apparatus.—The light is a revolving one, giving a single flash of eight seconds duration every minute. On account of the considerable altitude of the lighthouse, it was necessary to secure that a substantial quantity of light should be directed to the nearer sea; but it was also essential, on account of the exceptional power of the apparatus, that this dipping light should only be a small fraction of that sent to the horizon, otherwise its effect would be excessively dazzling. Many years ago, Mr. James T. Chance urged that it was not wise to make use of very small apparatus for the electric arc, because a larger apparatus renders it possible for the optical engineer to effect with greater precision the distribution of light which is most desirable, and because any trifling error which may occur in the position of the electric arc has, with the larger apparatus, a less marked effect on the light as seen from the sea. In the lighthouses of Souter Point, the South Foreland, and the Lizard, the third order apparatus of 500 millimetre focal length was adopted. Optically, the larger the apparatus used the better, but there might be some question whether, on purely optical grounds, the advantage of going beyond the third order is sufficient to justify

Fig. 1



the additional expense, but in the case of a revolving apparatus, the third order is a very inconvenient size for the service of the lamp; it is too large to be conveniently served from the outside, and too small to admit the attendant within it with comfort. With the large currents, which are now easily obtained and are likely to be used in lighthouses, a first or second order apparatus has the further advantage that it is less liable to injury from particles thrown off from the heated carbons. In the case of Macquarie, it was decided to adopt an apparatus of the first order, 920 millimetre focal length; it was further decided that the optical apparatus should produce its condensing effect by means of a single agent; that is to say, the vertical straight prisms which were used in Souter Point and other revolving electric lighthouses should be dispensed with. The condensation and distribution of light necessary may be obtained by means of a single agent, with apparatus such as has been proposed by Mr. Alan Brebner, Jun., Assoc. M. Inst. C.E.;[4] but this construction is open

to the objections that it is somewhat costly, and that it increases the length of the path of the rays through the glass, and consequent absorption. A practically better plan is to adopt forms not differing very greatly from those introduced by Fresnel; to specially arrange them for the purpose in hand, and to accept certain consequent minute deviations from a mathematically accurate solution, for the sake of advantages of greater importance, when all the actual conditions are taken into account. Figure 2 shows the optical apparatus in vertical section; the upper and the lower totally reflecting prisms are, as is usual in revolving lights, forms of revolutions about a horizontal axis; they direct the light incident upon them to the horizon and the distant sea from 10′ above the horizon to 30′ below; they are specially adjusted to distribute the light in azimuth over the arc of 3° necessary for a proper duration of flash.

The reflecting portion of the apparatus has the profile so calculated that the central lens, and the three rings next to the lens above and below, direct their light to the horizon without vertical divergence, except what is due to the size of the arc; the light for the nearer sea is obtained from the remaining ten lens-segments, Nos. 5 to 9 inclusive, above and below the centre, counting the centre as No. 1, the distribution being according to the following table, in which the first column gives the denomination of the elements of the lens in accordance with the numbers marked upon the section; the second, the angle between the direction of the sea horizon and the ray emerging from the upper limit of the element; the third, the angle between the direction of the sea horizon and the ray from the lower limit of the element, the negative sign denoting that the emerging ray is above the horizon. This practice, of appropriating certain elements of the apparatus to different distances on the sea, was first introduced by Mr. James. T. Chance, in the lights of the South Foreland, exhibited in January, 1872.

The ray, dipping at an angle of 7° 46′ 57″ below the horizon, will strike the sea at ½ mile, while 5° 8′ 52″ corresponds to ¾ mile, 2° 37′ 30″ to 1¼ mile, 1° 30′ to 2 miles, 1° to 2½ miles, and 30′ to about 4 miles. Thus the direct light begins at about ½ mile from the lighthouse. From ½ mile to ¾ mile the sea receives light from one element of the apparatus, from ¾ to 1¼ mile from two elements, from 1¼ mile to 2 miles from three elements, from 2 to 2½ miles from four elements, and beyond 2½ miles from six elements; the upper and lower totally reflecting prisms come in aid at about five miles. The main power of the apparatus is hardly attained till a distance of eight or ten miles. Figure 3 is a sectional plan of the apparatus by a horizontal plane through the focus. It will be seen that a dioptric mirror is placed on the landward side of the arc. This mirror is arranged to form the image of the arc at one side of the carbons, so avoiding the interception of light which would result if the mirror were used in the ordinary way, and contributing to the horizontal divergence necessary. Further horizontal divergence is given by the form of the lens. In the ordinary revolving light the inner face of the lens is plane; here it is cylindrical, the axis of the cylinder being vertical. This method of obtaining horizontal divergence is a modification of a proposal of Mr. Thomas

Stevenson,[5] M. Inst. C.E.; it is not mathematically accurate, inasmuch as the cylindrical form of the inner face of the lens not only displaces the emergent ray horizontally, but also in the case of rays not in the vertical nor horizontal plane through the focus, to a small extent vertically, but the error is easily calculable, and is unimportant, provided the lens is narrow, and the horizontal divergence of the beam moderate. Figure 4 shows a complete panel in elevation with revolving carriage. Figure 5 shows the plan of the service table of the pedestal and lamp table. A new construction was adopted for the gun-metal framework of the optical apparatus to reduce the interception of light by the frame to a minimum. The metal segment A, figure 6, forms part of the lower prism-frame, B part of the upper frame, whilst C and D are parts of the frame for the refracting portion of the apparatus; uprights E support the upper prism-frames without throwing weight on the lens frames. With the ordinary constructions of frame, figures 7 and 8, the equivalent of these ring segments A and B would intercept about double as much light as in this new construction.

Mechanism for rotation.—The pedestal is similar to those designed by Sir James Douglass to permit the light-keeper to obtain access from below to the interior of the apparatus without in any way interfering with its rotation. The clock work is fitted with the governor, and maintaining power used by Messrs. Chance Brothers & Co. for the last twelve years. The roller ring may be mentioned as of an improved type, for although it has been used for some years in all Messrs. Chance's lights, it has not been described before. The rollers and roller paths which carry the whole weight of the optical apparatus have long been made conical, so that the surfaces roll upon each other without twisting. There is consequently a very considerable radial force on each roller tending to force it outwards; the reaction against this force causes a very important part of the total frictional resistance. Figure 9 shows a portion of the roller ring and one of the conical rollers, according to the old construction, figures 10, 11, according to the improved construction; in the former it will be observed that the thrust of the roller is received on a collar; in the latter, on the end of a pin. The reduction of friction is practically very considerable, and although of small importance in a slow moving apparatus like Macquarie, is of great importance in heavier and quicker apparatus; for example, the triple-flashing light at Bull Point, in Devonshire.

Lamps.—These are of the Serrin type, and were supplied by Baron De Meritens.

Lamp table.—The arrangements for rapidly changing electric lamps, and for substituting gas or oil when desired, are shown in figures. 12, 13, 14 and 15.

weather, according to the opacity of the atmosphere; but the author understands that in practice the electric arc is always used. The paraffine oil lamp is intended as a resource in case of failure of the supply of gas.

Focussing the arc.—Two approximately rectangular prisms are fixed upon the mirror frame at about 90° from each other, the longer face of each is plane, the other two faces convex, of such curvature as to form a good image of the arc upon the service table, as shown in figure 16. During daylight, a pointed sight or focimeter is placed at the position of the image formed by the lens of an object on the horizon; this then is the position which the arc should occupy. A sight is next taken over the focimeter into one of the adjusting prisms, and a bright object such as a threepenny piece placed on the service table, is moved about until its centre is seen in the prism, exactly upon the point of the focimeter; a mark is made in the then position of the object. When the arc is correctly adjusted, its image on the service table will be at the point where the mark is made. Two prisms are used in order to secure that the arc shall be in the centre of the apparatus as well as at the correct level.

Lantern.—The lantern is of the well known Douglass type.[5]

Dynamo-electric machines.—Two alternate current machines, with permanent magnets manufactured by De Meritens, were supplied. Each machine has five rings in its armature, and in each ring there are 16 segments. In supplying one arc for a lighthouse the machine runs about 830 revolutions per minute, and gives a current of 55 amperes when half the coils are used, and of 110 when the whole of the machine is in action, the internal resistance in the two cases being 0.062 and 0.031 ohm. It is unnecessary to give a description of the machine as its general construction and dimensions are well known, but some numerical details are given below.

Engines.—Each machine is driven by an 8 h. p. Crossley gas engine through a belt without countershafting.

Tests.—Whilst the dynamo machines were at the works of Messrs. Chance Brothers and Co., a series of experiments was made in March 1881 to determine their properties. The time is long passed when it would be profitable to give the details of these experiments, but the general conclusions drawn at the time are still interesting. When the external resistance was a metallic conductor with small self-induction, it was found that with varying resistance and speed the currents observed agreed fairly well with calculation from the formula

$$\frac{A}{\sqrt{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2}},^6$$

in which R is the total resistance of the circuit, γ the self-induction, and T the periodic time. When the machine was running 830 revolutions per minute $A = 67$ volts and $\left(\frac{2\pi\gamma}{T}\right)^2 = 0.197$; hence $\gamma = 6.4 \times 10^5$ centimetres. The eighty sections of the machine are arranged four in series, twenty parallel. For a single section the value of γ would be $.32 \times 10^5$ centimetres. The maximum induction in the core, which has an area of five square centimetres, is 24,600 or 4,920 per square centimetre. The loss of power was greater when the machine was doing little or no external work than when that work was great. This is clearly seen in the following table:—

Current amperes	7.70	73.60
Electrical work horse-power	0.69	5.66
Mechanical work applied	3.09	6.55
Loss	2.40	0.89

Photometric experiments were made upon the arc, and simultaneous measurements of effective power applied and of current passing. The red light was measured through bright copper ruby glass, and the blue through a solution of sulphate of copper and ammonia. The horse-power was measured by a transmission dynamometer; but the results must be accepted with some reserve, on account of the difficulty of ascertaining the mean tension in a strap which is constantly varying. The oscillations of the dynamometer were damped by a dashpot containing tar.

	Half power.	Full power.
Red candles	1,988	4,708
Blue "	4,079	11,382
Current (amperes)	54.5	105
Mechanical power applied (h. p.)	4.5	6.9
Power expended in heating conducting wires (h. p.)	0.24	0.95

The results illustrate the fact that, as the current increases, the total light increases in a higher ratio, red light in a slightly higher ratio, and blue in a considerably higher.

The machinery for this lighthouse was sent out to New South Wales in November 1881, and was put up and started under the superintendence of Mr. J. Barnett, the architect of the colony, to whom is mainly due the success of the whole from the first start. The glare of the light upon the sky is said to have been seen at a distance of over 60 miles, far beyond the distance at which it would cease to be directly visible. The only criticism from mariners has been that when somewhat near the lighthouse the flashes are so bright as to dazzle the eye. This is an excellent proof of the power of the light, as a much smaller proportion of the light is directed upon the nearer sea than in any previous lighthouse. The lesson is that with powerful electric lighthouses almost all the light should, in ordinary weather at least, be directed to the horizon, and that the quantity thrown upon the nearer sea must be strictly limited. This is only possible when the focal length of the apparatus is large.

TINO.

This station is on a small island at the mouth of the Gulf of Spezia. Figure 17 is copied from the chart of the neighborhood. The focus is 386 feet above sea level. The distance of the sea horizon is 22.7 nautical miles, and the range practically 28 miles. The conditions, therefore, were very similar to those of Macquarie, with the exception that it was required to throw some light down into the channel between Palmaria and Tino. The lighthouse itself presents some interesting historical features. The buildings were originally a place of defense against the pirates who occasionally made descents upon the coast. Subsequently a coal fire lighthouse was established, and in the spring of 1885 part of the stock of lignite was still found to be in some of the buildings, where it had been lying for 50 years. In 1839 a dioptric light was established, one of the earliest of Fresnel's types, the lens ring being replaced by short straight prisms, which formed by no means a bad approximation, and could be ground without special machinery. The present electric lighthouse has been in contemplation for several years.

Optical apparatus.—The distinctive character of the light is a triple flash every half minute. The apparatus for producing this effect is of the general form introduced by the author in 1874. In October of that year he issued a pamphlet pointing out the several advantages of group-flashing lights, showing for the first time a simple dioptric apparatus suitable to their production, and also pointing out how easy it is to give the group-flashing effect with catoptric apparatus. Since that time a large number of dioptric group-flashing lights have been made by Messrs. Chance Brothers and Co., and some also in France, and Mr. Allard has incorporated group-flashing lights in the system of distinctions he recommends; also a considerable proportion of the light-vessels on the English coasts have been converted into group-flashing lights of the catoptric system. On the ground of economy the second order apparatus

of 700 millimeter focus was adopted in the case of Tino. It is just large enough for tolerably convenient service of the lamp by an attendant entering within the apparatus. The apparatus, shown in vertical section in figure 18, and in horizontal section through the focus in figure 19, has 24 sides, eight groups of three; one group of three is shown in elevation in figure 20. The horizontal divergence is obtained in exactly the same way as at Macquarie, excepting that no mirror is used. The metal framework, however, approximates to the ordinary type, as the type used at Macquarie would have been costly when applied to a triple-flash light. The distribution of light vertically is as follows: upper and lower prisms, and the central lens, with the two lens rings next adjoining it, all to the horizon and most distant sea. The lens and lens rings direct their rays according to the following table, which is arranged in exactly the same way as the table already given for Macquarie:—

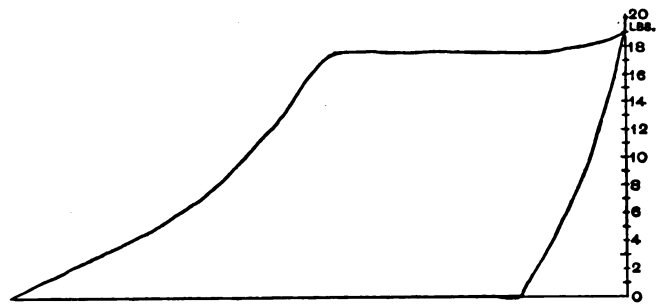
I.	II.	III.
	° ′ ″	° ′ ″
7 top	0 31 35	8 16 0
6 "	"	2 0 0
5 "	"	1 30 0
4 "	"	1 0 0
4 bottom	"	0 45 0
5 "	"	0 30 0
6 "	"	0 30 0
7 "	all to the horizon.	

No. 7 bottom was directed wholly to the horizon, in order to avoid the horizontal bar of the lantern. It will be observed that the quantity of light thrown upon the nearer sea is much less in the case of Tino than in that of Macquarie, and that greater reliance is placed upon the accuracy with which the arc can be kept in focus; experience has justified these changes, as improvements of a perfectly safe nature.

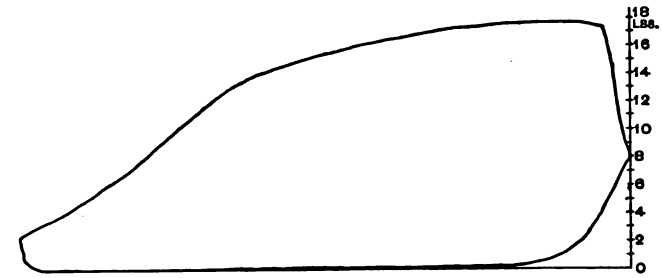
A small part of each flash is bent downwards and distributed over the channel between Tino and Palmaria, by means of subsidiary prisms fixed upon the lantern, shown at x, figure 18. These subsidiary prisms are really superfluous, as the scattered light from the beams overhead is found to be as effective at this short distance. Figure 21 shows the plan of lamp shunting table and service table.

Engines.—As there is no water upon the island, the practice of the Trinity House was followed, and two of the Brown hot air engines were supplied, each driving through a countershaft one of the machines. The countershafts could be connected by means of a Mather and Platt friction coupling, so that the two machines could be driven together, or either machine from either engine. Drawings of the Brown engines are given in Sir James Douglass' paper.[7] The accompanying indicator diagrams were taken from the compressing and working cylinders. Whilst these diagrams were taken, the effective power developed was measured by a friction brake on the driving pulley, and was found to be 9.1 h. p. Thus of 33.1 h. p. indicated in the working cylinder, 17.7 h. p. is employed in compressing the air, 6.3 h. p. is wasted in friction in various parts of the machine, and only 9.1 h. p. is effective upon the brake. The engines consume about four pounds of coke per effective horse-power per hour. In future lighthouses, when a steam engine cannot be employed, it would be preferable on every ground to use gas engines, and manufacture on the spot either Dowson gas or ordinary gas, according to the character of the fuel available.

Dynamo machines.—There are two machines of exactly the same type as those supplied for Macquarie, the only novelty lying in the method of using them. In 1868 Mr. Wilde discovered, by experiment, that two alternate current dynamos, independently driven at the same speed, would, if electrically connected, so control each other's motions that they would add their currents. The author subsequently arrived at the same conclusion independently, on theoretical grounds, and gave a thorough explanation of the fact.[8] The result has been put to a practical application at Tino. The machines are connected to a single switchboard, so that each half of the two machines can at pleasure be connected to, or disconnected from, the main conductors. Thus a current can be supplied from either machine at half power, 55 amperes, or full power, 110 amperes, or from the two machines of double power, or about 200 amperes. Further, a change can be made without extinction of the light from one dynamo and engine to the other. Thus, suppose one machine is working at full power, clutch the countershafts gradually together, so starting the second engine; throw on the band of the second machine, cut out half the first machine, and connect half the second machine at the switchboard; the two machines at once synchronize, without affecting the light. Disconnect the remaining half of the first machine, and connect the remaining half of the second, unclutch the countershafts, and stop the first engine. One man can effect the change, with no more disturbance of the light than a change from full to half power for about one second. A further conclusion, deduced from theoretical considerations, was that of two alternate current machines of



Compressor pump-cylinder, 24 inches in diameter. Stroke, 22 inches. Indicated h.p., 17.7.



Working-cylinder, 32 inches in diameter. Stroke, 20 inches. Indicated h.p., 33.1. Revolutions per minute, 64. Power on brake on fly-wheel, 9.12 h.p. Pressure in reservoir, 19 to 24 lbs.

equal potential, one could be used as a generator of electricity, the other as a motor converting the current generated back into mechanical power. It was found impossible to verify this conclusion with such intermittent driving as that of a hot air engine. But Prof. W. G. Adams effected the verification without difficulty at the South Foreland, the motive power being steam.

Lamps.—These are the improved Serrin of Mr. Berjot. One of the three lamps supplied is of larger size, for the double power current from the two machines. This lamp was said to be suitable for a still greater current, but with about 200 amperes it soon became dangerously heated; a simple modification rendered the lamp equal to the actual work it had to do. It is, however, probable that for the occasional circumstances when it is necessary to use so great a current as 200 amperes in a lighthouse, a lamp worked partly by hand would be preferable to a regulator entirely automatic.

The apparatus was delivered in November 1884, and

was put up by workmen from Messrs. Chance's workshops, under the supervision of Mr. L. Luiggi, of Genoa, to whose ability and energy the complete success of the lighthouse is largely due. A complete test of the performance of the light, as seen from the sea in all grades of its power, was made in April 1885 by a commission consisting of Prof. Garibaldi, of Genoa; Mr. Giaccone, engineer-in-chief for Italian lighthouses; Captain Sartoris, and Mr. Luiggi, the author attending on behalf of Messrs. Chance. The light was well observed through rain, when distant 32 nautical miles, and although below the horizon, the position was precisely localized, and the triple-flash distinction unmistakable. At 18 miles distant the illumination of the flash upon white paper was sufficient to make out letters marked in pencil 1¼ inch high, and when 14 miles distant it was easy to ascertain the time from a watch. The light is frequently seen at a distance of 50 miles, near to Genoa.

A review of work which has been carried out naturally suggests many questions as to what conclusions experience has established, and what indications it gives of the probable direction for future developments. In the use of electric light in lighthouses, there are many questions upon which there is wide difference of opinion, questions both as to when and where electric light should be adopted, and questions as to the best way of employing it. It may not be unprofitable to allude to some of them. Although English engineers are now well agreed that a large optical apparatus should be used for the electric light, this opinion is not universally accepted. The advantages of a large apparatus have already been mentioned. To balance them, there is nothing on the other side but the less prime cost of the smaller apparatus. Although the difference of cost appears considerable when attention is confined to the optical apparatus, it is unimportant when the whole outlay on the lighthouse is brought into account. Cases are, however, conceivable in which a small optical apparatus such as a fourth order, having a focal distance of 250 millimeters, would be properly preferred; such, for example, as a harbor light which could be supplied with current from machinery also used for other purposes, but such cases are likely to be exceptional.

When a flame from oil or gas is the source of light, there is of necessity a considerable divergence vertically; and the distribution of the light through the angle of vertical divergence is not at disposal, except to a very limited extent in some cases, but is determined by the size and character of the flame. With the electric arc and a large optical apparatus it can be determined in considerable measure how the light shall be distributed—how much shall be sent to the distant sea, how much to the various distances between the foot of the tower and a distance of some miles. It becomes then a question what use is to be made of this facility. The experience at Macquarie and at Tino is emphatic, that it is in every way advantageous to direct much the greater part of the light to the horizon with a very small divergence, and to distribute the comparatively small remainder over the nearer sea with intensity increasing with the distance.

A question allied to the last is this: Whether it be desirable to provide means of directing the strongest light downwards on to the nearer sea in time of fog? The answer must depend upon the circumstances of the particular locality. Take the case of a lighthouse on an isolated rock, the purpose of which is primarily to be a beacon to keep ships off that rock; a lighthouse which would not exist were it not more practical or cheaper to build and maintain the lighthouse rather than remove the rock. Here surely it is of the greatest use to provide means whereby, if the light cannot penetrate two miles, it shall if possible be visible at one mile. But other cases occur in which the lighthouse has to cover a long length of coast, and has almost as much to do with points of the coast 10 miles distant as with the point upon which it is placed, cases in which the lighthouse is far more useful in guiding the regular traffic passing within a radius of 20 miles or more, than in preventing vessels running ashore within a mile of the tower. Such a light fails of its purpose if it can only be seen at a distance of a mile, covering less than $\frac{1}{100}$ part of its normal area of illumination; it becomes comparatively useless unless it penetrates to something like its normal range, and its efficiency must be measured by the fewness of the occasions when it fails to do this. It is a grave question whether it be prudent in such cases to place upon the light-keeper the responsibility of judging when the light should be dipped on to the nearer sea, the fact being that, if his judgment errs, he may actually diminish the range of the light, and cause unnecessarily the lighthouse to fail of fulfilling its most important function. It is easy for him to be misled if the fog is local and does not extend to any great distance from the lighthouse. Another element enters into the consideration—the height above the sea. If the focus be 100 feet above the sea level, the dip of the sea horizon is 9′ 45″, and a ray dipping 9′ 45″ below the sea horizon will meet the sea at a distance of 3.1 nautical miles from the tower. Even with a first order apparatus, if the arc be a powerful one, it is very difficult to render the light directed to the horizon from an elevation of 100 feet more powerful than that directed to a point distant four miles from the tower. Unavoidable divergence will render the two intensities practically equal.

Passing to questions of another class, what are the relative advantages in an electric lighthouse of continuous and alternating currents? Present practice tends altogether in favor of alternate currents, but this practice largely results from unfavorable experience of the older continuous-current machines. These machines have in many respects been greatly improved in the last two or three years. The continuous current presents the advantage of greater economy of power in producing the current, less floor space required by the machine, and a smaller prime cost. The alternate-current magneto machine, on the other hand, has the advantage that it may be driven with a defectively governed prime mover, with an indifferent lamp, and may suffer neglect with impunity; whereas the more compact and efficient continuous-current machine would be in serious peril of destruction. Optical apparatus can be constructed suitable to make the most of either form of arc. Hot air engines have found favor for electric lighthouses, because in many cases there is no available supply of fresh water. The engines of which the author has experience are open to the objection that they take a great deal of room, are not economical of fuel, and do not govern so quickly as is desirable; the wear and tear also, when they are worked to anything like their full power, is very serious. A gas engine, with Dowson or other gas made on the spot, could be used with greater advantage.

Antecedent to all considerations as to the best apparatus and machinery to be used, is the question, under what circumstances, if at all, should electric light be used in a lighthouse? The Trinity House experiments at the South Foreland showed to demonstration that, where the issue to be decided was how to produce a light which should be capable of penetrating the furthest in all weathers, electric light could do that which could be done in no other way, and that it was the cheapest light of all when the price is estimated per unit of light. But the conclusion was also reached that an electric light must inevitably cost a large sum, both in first outlay and in maintenance; therefore that electric light is extravagant unless very extraordinary power is a necessity. This conclusion is doubtless a fair consequence of experience, but it is not an inherent property of electric light. Both the capital outlay and the cost of maintenance are greatly increased by the practice of so arranging the machinery as to provide, at all times, a light of very great power: whence follows that the machinery must be placed at some distance from the lantern, and two men

Digitized by Google

must always be on duty; one man in the lantern, and another with the machinery.

The essentials for a cheap electric lighthouse are, that for ordinary states of the atmosphere there shall be provided a plant under the easy control of the light-keeper himself, which shall be precisely adapted to produce that amount of light which is wanted in ordinary states of the atmosphere; but for thick weather there shall be provided a much more powerful engine and dynamo, available also as a reserve in case the smaller machinery from any cause breaks down. The occasional machinery may be more remote from the lantern, as it is a small matter to require a second man to work on the comparatively rare occasions when the maximum power is needed. A small gas engine and a dynamo machine can be placed without any crowding in the room immediately below the lantern, and arrangements can be made whereby the light-keeper, whether he is in the lantern or in the engine room, can ascertain at a glance whether the arc is in its proper position, with an error of less than one millimeter. The attendance on the lamp, rotating apparatus of the lens (if a revolving light), engine and dynamo, would be easy when the whole is brought together, so as to be under observation at once; in fact the gas engine, dynamo, and lamp constitute together a gas burner which, though consisting of many parts, is automatic throughout, and requires nothing but the constant presence of a custodian, exactly as the gas lamp in a lighthouse requires a custodian, as a guarantee against failure. The same end, viz., the concentration of the whole mechanical and electrical apparatus under one pair of eyes, could be attained, of course, in other ways. Accumulators could be used, or a petroleum engine.

In order to give definiteness and afford facilities for criticism, the better course will be to describe a suitable machinery; state what it will do, what attendance it will require, and what it will cost. The author proposes, then, for an electrical lighthouse where small outlay is essential, the following:—A Dowson gas producing apparatus and gas holder, the generator and superheater being in duplicate, each capable of making 1,200 feet of gas per hour, the gas holder having a capacity of 3,000 cubic feet.

An 8 h. p. nominal Otto gas engine and series-wound dynamo machine, placed in a room near the base of the tower, and copper conductors to the lantern, the dynamo having magnet coils, divided into sections so as to supply a small current when required.

A 1 h. p. nominal Otto gas engine and dynamo machine, placed in the room immediately beneath the lantern floor, with gas pipe from the gas holder; three electric lamps, to receive either carbons 25 millimeters in diameter or any lesser size, with complete adjustments for accurate focussing; one paraffine lamp as a substitute; an optical apparatus of the second order of 70 centimeter focal distance. The cost of this apparatus would depend upon the character of the light it was intended to exhibit. To fix ideas, let it be assumed that the light is to be a half-minute revolving light, showing all round the lighthouse. There could then be supplied a sixteen-sided apparatus with pedestal and revolving machinery. Provision would be made in the optical apparatus for giving the horizontal and vertical divergence desired by the same methods successfully used in the lighthouses of Macquarie and of Tino.

Two focussing prisms would be fixed to form magnified images of the arc, on pieces of obscured glass let into the pedestal floor, so that the keeper, whether in the lantern or in the engine room, could see at a glance the state of the arc, and observe whether it is of proper length with the carbons in line, whether it is exactly at the right height and in the centre of the apparatus. An error of one millimeter would be glaringly apparent, and call for immediate adjustment, although its effect would be only a displacement of the beam 5′ of angle.

The lantern would be 10 feet diameter, with bent plate glass.

The cost of the whole above described would be materially less than the cost of a first order light and lantern with oil lamp and large burners.

Now what result would be obtained? In fine weather the small engine would be used. Its effective power on the brake is fully 1½ h. p.; from this 1½ h. p. the dynamo machine produces considerably over 800 watts, say 800 watts in the arc itself, or 20 amperes through a fairly long arc of 40 volts. Of course the value of this in candles depends upon the color in which it is measured, and the direction in relation to the axis of the carbons. In red light the mean over the sphere would certainly exceed 1,200 candles. In clear weather or in slight haze or rain, the beam of this light through the lenses would be much more powerful at the horizon and on the more distant sea than any single focus light with oil or gas as the illuminant, and would at least be fairly comparable with anything yet exhibited with oil or gas whether triform or quadriform. But on the nearer sea the illumination would be reduced, so that no annoyance would be caused by dazzling flashes. In thick weather, or indeed in any weather when there was a doubt as to the visibility at the horizon of the lower power, the large engine would be used under the superintendence of the second keeper. This engine will give 10 h. p. on the brake, and there is no difficulty in obtaining 85 per cent. of this as useful electrical energy outside the machine, that is 6,340 watts. From this deduct 10 per cent. for the leads and the lamp and for steadying the arc, leaving 5,710 watts in the arc itself, or 114 amperes, with a difference of potential of 50 volts. Having regard to the fact that the optical apparatus here proposed acts upon a larger portion of the sphere than that used in the South Foreland experiments, that the vertical divergence is less, and that the potential difference is greater and the current continuous, although less in quantity, it may safely be assumed that the power of the resulting beam would not be inferior. It hence follows, from the South Foreland experiments, that in any fog the flashes would penetrate farther than those of any existing gas or oil light. The increased size of crater, compared with that produced by the current of 20 amperes, will give increased vertical divergence, and so cause the maximum illumination to be attained at a less distance from the lighthouse. The attendance of two men would suffice for all the duties of the lighthouse, because under ordinary circumstances one man only need be on duty excepting for two to three hours whilst gas is being made. The consumption of coal would be 4 lbs. per hour of lighting, of water about one-half gallon, of carbons about four inches. The whole cost of maintaining the light would differ little from that of an ordinary oil light of the first order.

Though it be the fact, that it is possible to exhibit an electric light at moderate cost, it does not follow that it is suitable for all ocean lights. There is no room in a rock lighthouse tower for a gas plant, and few would at present be prepared to recommend a petroleum engine burning oil of a low flashing point. The light-keeper again must understand a gas producer, a gas engine, a dynamo and an arc lamp, instead of only a paraffine lamp and burner, and arrangements must exist for repairing the more extensive machinery. Such considerations will justly weigh against the use of the electric light in remote stations and in countries where the labor available is not capable of much training.

It may possibly be said that in this paper no definite conclusions are reached as to whether electricity or some other agent is the best source of light in lighthouses generally, nor yet, if electricity be adopted, what is the best way of producing the light and optically dealing with it. The answer is that it is impossible on many points to arrive at general conclusions. Each case must be judged according to its special circumstances.

The paper is accompanied by a lithograph and tracings, from which the figures in the text have been prepared.

THE SHORT-NESMITH ELECTRIC RAILWAY.

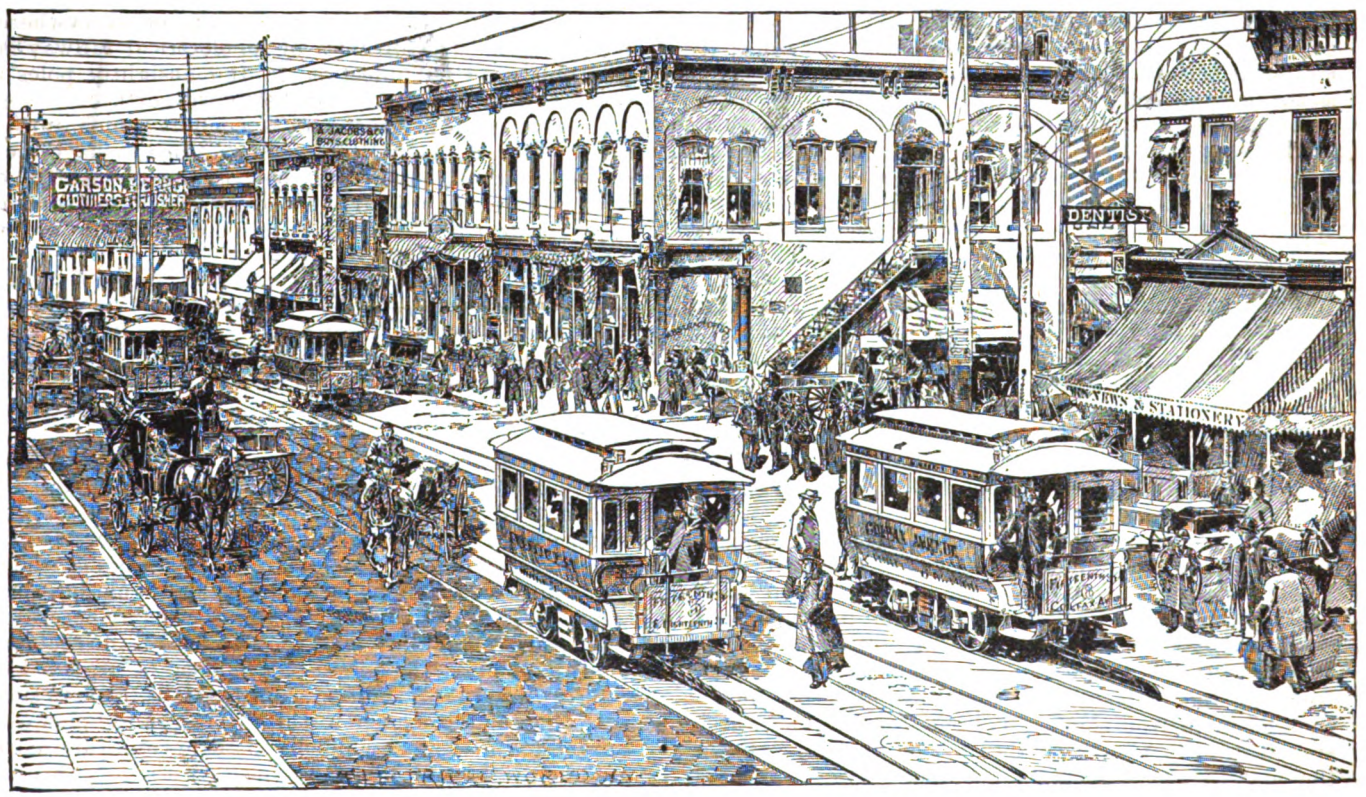
A NEW SYSTEM IN WHICH THE CARS ARE RUN IN SERIES ON A SINGLE LINE CONDUCTOR.

In the month of April 1885 a company was organized in Denver, Colorado, under the name of the Denver Electric and Cable Railway Co.

This company was formed for the purpose of building and operating an electrical railway in the streets of Denver. It at once adopted a plan proposed by Sidney H. Short, then professor of physics in the University of Colorado, Denver.

Mr. Short called the attention of the gentlemen comprising this company to his series system of electrical railway, and a small piece of track, between three and four hundred feet, was laid in a circle in the university grounds. A small car, named Joseph Henry, was built, and carried many hundreds of people over the track.

The success of this little road encouraged the company to make more extended experiments in this direction.



Electric Railway Cars on Fifteenth Street, Denver, Colorado.

This first road was built on the following plan. Two bare conductors were laid side by side along the track in a small conduit placed between the rails. The conductors were small and supported on insulators attached to the cross ties. The conductors were cut into sections in order to test the working of this system of conductors. Switches operated by the current connected the two conductors in multiple arc, making them practically one conductor having the conductivity and sectional area of the two. These electrical switches at the same time connected the ends of the sections of this double conductor making one continuous conductor along the entire length of the track. The ends of this working conductor were connected by means of wires with the dynamo. When a car was placed on the track and had its brushes or contact springs one on each of the parallel conductors of any section, the electrical switches at each end of that section would at once disconnect one of these conductors at one end and the other at the other end, leaving the only path for the current along one conductor through the motor to the other conductor and the line again. These sections could be made any convenient length from that of an ordinary car to a block or a mile. A car could be on every section and the same current pass through all of them.

Mr. Short maintained that the only way to make a successful electrical railway was to use a constant current of small quantity; run the cars in series like arc lamps or telegraph instruments, and vary the electromotive force with the power required to operate the line of road. This principle has not been in the least varied from since the enterprise was begun, but many modifications in the details of construction have been made from time to time.

The two conductors used in this arrangement were intended to carry the current in the same direction at the same time along the track and, as stated before, they became electrically one conductor. At the junction of two sections there were four contacts to be operated by an electrical circuit closer which was necessarily a complex and delicate piece of mechanism to keep in good working order, especially when placed on the street where it was liable to injury. Mr. Short at once began to devise some means of combining the two wires into one in order to do away with one pair of contacts at the junction of the sections and also to lessen by half the chance for leakage from the insulating supports. He found only one thing to do—shorten the sections of the conductor to the length of one car or train of cars. This increased the number of circuit closers greatly, but at the same time increased the flexibility of the road as cars could be run as close together as they could be placed on the track.

A contact brush must be placed under each end of the car or train of cars to make electrical connection with the conductor, so that there will always be a circuit closer between these brushes, as shown in figure 1. The circuit closer between these two brushes must, however, be kept open as long as it remains between these brushes and must close the line as soon as the brushes pass beyond it. Electrical means for accomplishing this were devised, but it was open to the same objection as the one referred to above, and with the large increase in the number this

Digitized by Google

objection became still greater. A mechanical circuit breaker must be provided. Mr. Short presented this problem to Mr. John W. Nesmith, a practical mechanic of long experience and of much ingenuity, and asked him to devise some mechanical plan for keeping the spring or circuit closer, shown in figure 1, open so long as the car was over it. Mr. Nesmith proposed that a long slender bar of insulating material be stretched between the two current collectors or brushes, this bar to slide between the contacts at the ends of the sections of the conductor, and keep them apart so long as the car is passing, as shown in figure

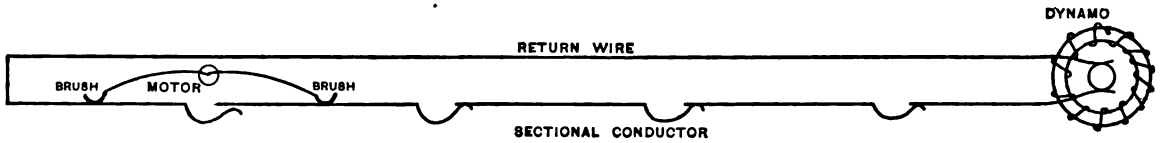


FIGURE 1.

2. In July 1885, this second plan was tried on about three hundred feet of track with the same car used in the first experiment. A brush at each end of the car made contact with two sections of the conductor; a leather strap stretched between the two brushes kept the springs apart as the car passed over the circuit closer. This experiment was a perfect success and the desired end was obtained.

The Denver Electric and Cable Railway Co. at once ordered the material to lay one-half mile of track upon this plan, and also two motors and one dynamo of the Short type. A small engine made by the Colorado Iron Works,

The experience of a few days showed this plan to be impracticable on account of the difficulty of keeping this conductor insulated, and the further difficulty that a very little sand and dust in the tube stopped the brushes. The most serious trouble to overcome was the leakage due to imperfect insulation. This has been and is to-day, one of the chief obstacles in the way of the practical operation of any form of electrical street railway. It requires much and careful study on the part of electrical engineers. This difficulty has driven most of the electrical railway conductors overhead on poles, making these systems impracticable for large cities. A conduit system must eventually be used in the streets of even small cities, the objection to overhead electric wires of any kind being everywhere on the increase. The inventor of an electrical railway must face this growing objection to the unsightly poles and wires, and put his conductors below the surface.

In wet, muddy streets, in a conduit which must be small and must be built of iron or stone to have the required strength, how will it be possible to insulate conductors, bare throughout their entire length and supported every few feet? Mr. Nesmith proposed to use an ordinary

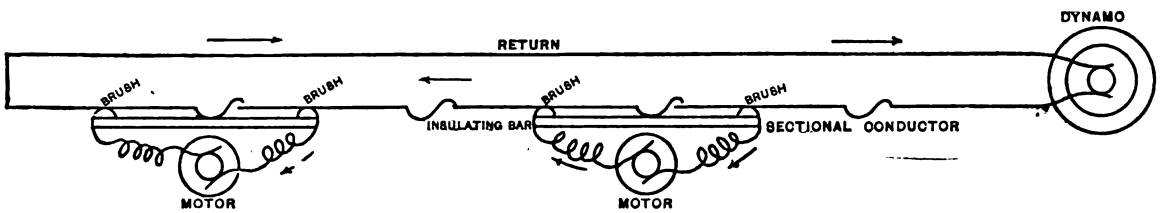

FIGURE 2.

of which Mr. Nesmith is president, was put in place near one end of the line. This engine was of the ordinary slide valve form with a cylinder 9″ x 12″. Two elegant coaches were built by Woeber Brothers in Denver. The conductor used in this trial was a slotted copper tube about one inch inside diameter. Each tube was about 16 feet long and embedded in asphaltum and tar, the whole encased in an iron shell, a slot cut through, and was then spiked to the ties, with the slot at the top. Between the ends of these sectional conductors were mechanical contact closers. The car was provided with a contact

underground cable to be laid in the ground outside of the conduit—leaving the conduit for the passage of the current collecting brushes. Mechanical circuit closing springs were to be used in the conduit at intervals as before. By this arrangement only the exposed ends of the sections of the conductor at the circuit closers must be provided with careful insulation. This was a great step towards success with the conduit system. This change in the plan of the conductors made a new device for connecting the current gatherers necessary. It must consist of the long insulating bar to keep the circuit closers open, and also of some device

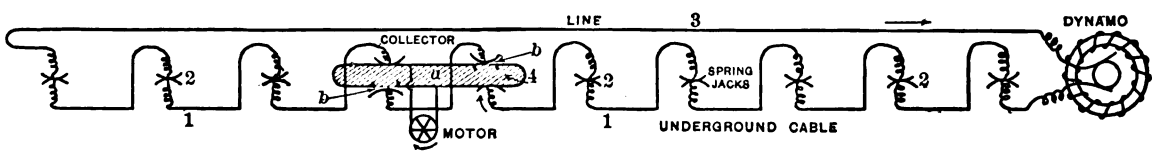

FIGURE 3.

2, CONTACT SPRINGS (SPRING JACKS). 4, CURRENT COLLECTOR. *b*, CIRCUIT BREAKER.

brush at each end which fitted into the tubular conductor like a gun-wiper brush. Between these brushes was stretched a long flexible rubber cylinder which almost filled the tube. As the car moved along, the forward brush was pushed through the tube and contacts at the ends, the rubber rod followed and kept the contacts apart until the rear brush had passed, and the current was forced to pass from one brush through the motor and back to the other brush. In October 1885, this half mile was completed, and for the first time a car driven by electricity made its appearance on Fifteenth street in Denver.

for always diverting the current from the line through the motor on the car. At the same time it must neither short circuit the motor out of the line, nor open the circuit of the line, for in the first instance the motor would stop, and in the second the current collector and circuit breaker would be destroyed by flashing, and the insulation of the generator and underground wire would be endangered.

Mr. Short took this matter in hand and devised a very ingenious electrical current collector which has gained the name of "arrow" from its form. Figure 3 shows the line with the current gatherer; figure 4, the construction of

Digitized by Google

the current gatherer, and figure 5 the current gatherer in a circuit closer. 4, 5 and 6, figure 4, are three sections of the underground cable connected with the two circuit breakers B and B. If the current gatherer were removed from the breakers B and B, these breakers would close and the line be continuous. This current collector is made of a slender bar of insulating material somewhat longer than the section of the conductor between circuit closers. The metal strips 1 and 2 are fastened around the entire edge of the insulating bar except at 3 and 3, where there are short insulated breaks in them as shown. Wires pass from these metal strips 1 and 2 to the motor. The current passes into strip 2 from section 5 of the conductor through the motor into strip 1, and out on the other section at 6, as shown in the figure. The middle section, 4, of the house and the post office. Ordinary cross-ties were used, upon which were laid 20 pound T rails. Notches were cut in the centre of the ties to form the conduit through which the arrow or current collector should pass. Planks were spiked to the ties covering the notches, except a small slot in the centre. The edge of this slot was protected by strap iron nailed to the planks. Under one of these planks was laid a Waring lead encased cable, with a conductor of No. 3 B. and S. gauge. Circuit breakers were placed every 25 feet, and the cable cut and attached to them. The two coaches built in Denver were placed upon the track. Each car had a motor of the Short type, made in Denver, and was supplied with both reversing gear and speed gear. Each motor weighed about 1,500 pounds. Tests were made of the efficiency of these motors when

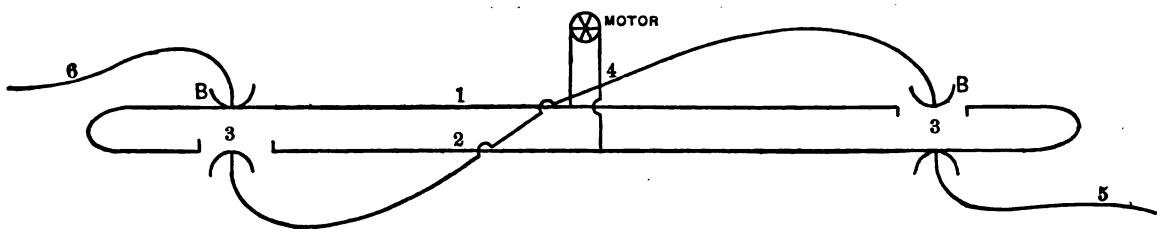

FIGURE 4.

conductor is cut out of circuit when the current collector is in the position shown in the figure. If the arrow be moved in either direction it will be seen that no flashing can occur, neither can the line be short circuited. This current collector is 2½″ by 1½″ in section and about the length of a car. It is supported in the conduit by attachments passing down through the slot.

In November 1885 this company put down on the same street 500 feet of the new line of insulated wire for one of these current collectors. It worked perfectly. During this entire winter of 1885 and 1886, this little line was worked in all kinds of weather—snow, rain and mud—the track was flooded. The severest tests possible were made to prove its merits and it never failed.

The Denver Electric and Cable Railway Co. had procured from Mr. Short, the right to use and manufacture for its own use all the electrical railway appliances of his they were developing from 5 to 8 h. p., with a current of 25 amperes, and they showed an efficiency of 80 per cent., *i. e.*, for 10 h. p. of electrical energy put into them, they returned 8 h. p. at the Prony brake placed on the armature shaft. This is the average of many tests. The motors were placed on frames which were hung from the axles of the car trucks and carefully insulated from them. On the armature shaft of each motor was placed a raw-hide pinion. This pinion drove an iron gear on a counter shaft which had its bearings attached to the same frame. The counter shaft carried another pinion which meshed with the large gear of the driving axle of the car. This method of gearing was direct and positive, made little noise, and admitted of a simple and efficient reduction of speed from the motor armature shaft to that of the car axle. The small engine and dynamo first placed in the plant were used to furnish the power. On the 31st of July,

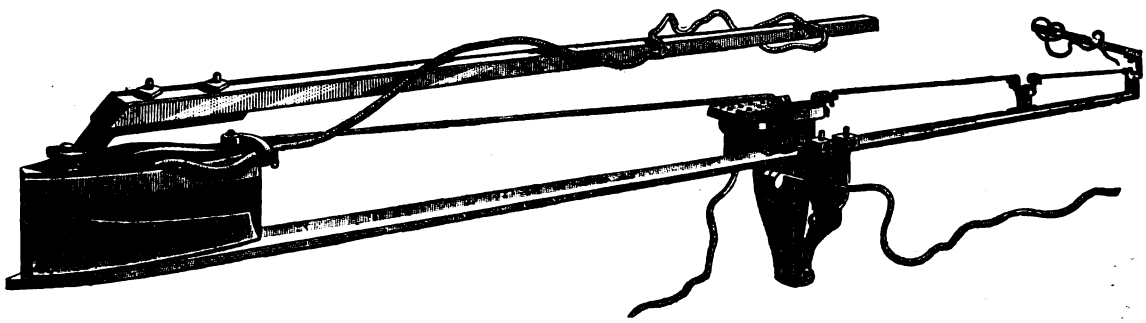

FIGURE 5.

invention in the state of Colorado. A new company, the United States Electric Co., comprising many of the gentlemen in the local company was organized in August of 1885, for the purpose of developing Mr. Short's inventions. They secured his services as electrical engineer, and have arranged to own and control throughout the world his inventions, together with those of Mr. Nesmith.

The officers of this company are, Mr. Wm. N. Byers, president; Sidney H. Short, electrician and electrical engineer; John W. Nesmith, mechanician; Edward Grace, secretary.

In June and July of 1886, the new company put down under contract 3,100 feet of electrical railway, upon the last plan, for the Denver Electric and Cable Railway Co. This track was laid on Fifteenth street between the court this road was started, and the car moved from one end of the track to the other without a hitch. This road was run constantly for three months, two men being required to operate it, one at the engine and one on the car. Only one car was run regularly as the line was so short. This car made six round trips per hour on a running time of 15 hours per day. No difficulty was experienced in operating this road. The success of the system and the enterprise was assured.

In the meantime, the Denver Electric and Cable Railway Co. consolidated with another company, The Denver Railway Association, and the new company took the name of the Denver Tramway Co. This company contracted with the Denver Tramway Construction Co. for the equipment of its lines with the improved system of electrical railway.

Digitized by Google

The work was immediately begun, and 3½ miles are now fully equipped and in operation with seven cars. A new conduit of cast-iron was used, and the slot narrowed to five-eighths of an inch. The conduit was enlarged to 7″ by 5″ and made more substantial and durable. As Denver streets are not paved it is difficult to construct a good road-bed. Large buildings have been erected, and a Lane and Bodley 16 by 42 Corliss engine put in place. A 100 h. p. Brush dynamo and a 100 h. p. Short automatic dynamo for constant current were added to the plant. Five Brush motors were placed under as many new cars, and the last of November the new machinery was started.

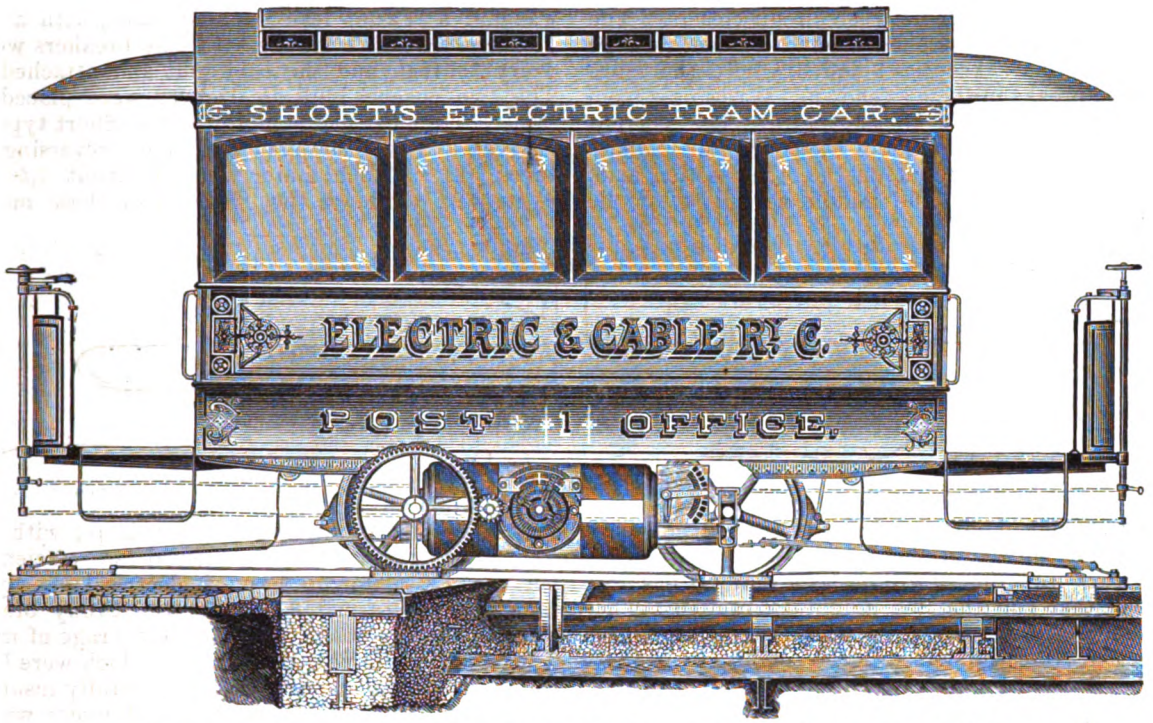

FIGURE 6.—SHOWING SECTION OF CAR TRUCK AND CONDUIT, WITH COLLECTORS IN POSITION.

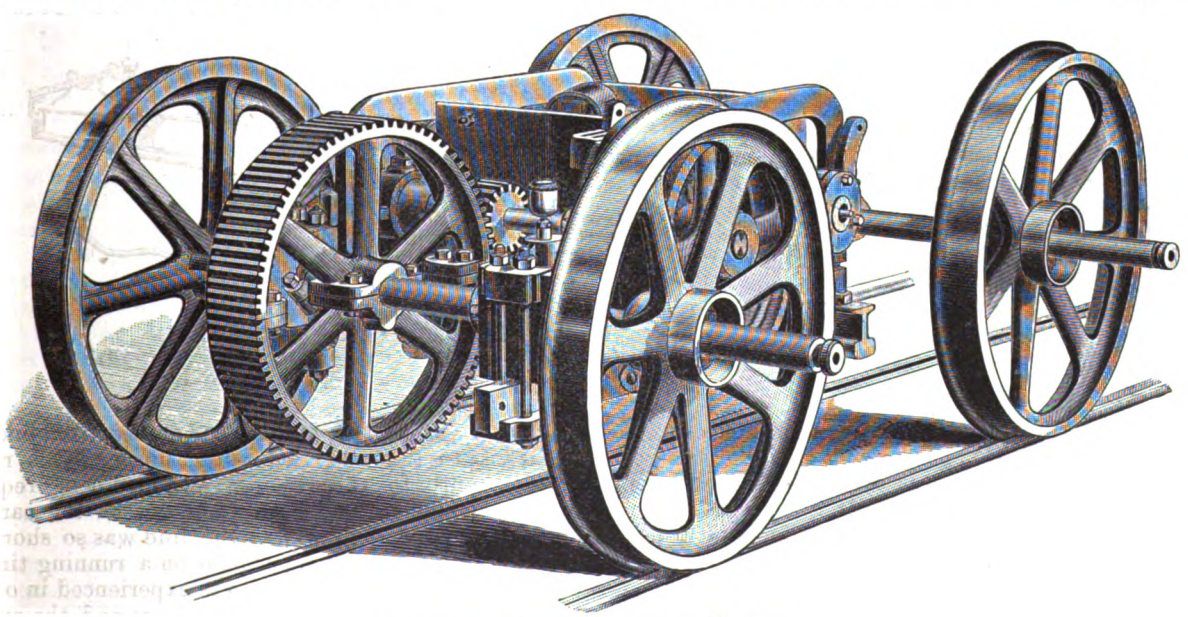

FIGURE 7.—MOTOR, TRUCK AND GEARING.

The road now in operation comprises some of the most difficult problems in electrical railroading. Starting as it does in the east end of Denver, on top of Capitol Hill, a single track passes down a grade of 350 feet to the mile. At the bottom of the hill it crosses two horse car tracks, then curves into Fifteenth street. When it reaches the court house it divides into a double track with automatic slot and track switches, which always turn the down car upon the right hand track. The double track continues for three-fourths of a mile, and on its way crosses five horse car tracks, two on curves. It then returns to a single track with automatic switches. This single track crosses five steam railway tracks, then enters a turnout, crosses another horse car track, and crosses the river as a double track on a bridge 200 feet long, two more steam railway tracks and another horse car track. Again it becomes a single track and branches into two lines, one going to the north, the other to the east, and climbs a grade of 350 feet to a mile, and about two blocks in length.

This line of track takes the cars across the city through the most densely settled business portion, where the traffic is heavy. The road has been running through the severest

Digitized by Google

winter weather. A heavy snow fell soon after the road started, and snow plows were put on the cars, which cleared the track perfectly while making their regular trips. Each car is provided with sand boxes and sand pipes, and the track can be sanded from either end of the car by the driver.

The driver has a simple handle which is placed on an upright shaft in front of the dash board of the car with which he controls the speed and reverses the motion of the car. The cars pass a given point going in the same direction every ten minutes, making an average speed of six miles per hour. However, cars have been run over the line at night when the streets were clear, at the rate of 25 miles per hour.

The trucks and gearing, figure 7, used in this system are of the simplest kind. The ordinary street car wheels and axles are provided with an iron frame supported upon spring pedestals. On this frame the motor is fastened. On the shaft of the motor is a pinion which drives a gear-wheel on a short counter shaft. This counter shaft carries another pinion which meshes with a large toothed gear wheel keyed to the axle of the car wheel. The greatest difference between pinion and gear being as one to five. Very little noise is noticed. The motor and its mechanical connections being wholly mounted on the truck, independently of the body of the car, the system can be readily applied without remodeling materially the cars now in use on horse car lines.

The conduit shown in figure 8 is so arranged as to admit of its being put down on existing horse car lines. It is only necessary to remove the pavement in the centre of the track, dig a trench down to the cross-ties and put down the cast-iron conduit, which is made complete in sections of eight feet. Before the pavement is relaid the lead encased cable is laid along at one side, as shown in the cut, all insulated and complete. The change from horses to electricity can by this method be made without interfering with the traffic of the road in the least.

The same current which feeds the motor is used to light the cars with incandescent lamps and to operate an alarm bell to warn persons of the approach of the cars. The cars can be moved forward or backward, and can be governed from either platform.

A few days since indicator cards were taken from the engine while three cars were in service, which showed an average of 32 h. p. delivered to the driving belt. A constant current of 40 amperes was passing over five miles of No. 3 B & S gauge conductor.

The resistance of the circuit is seven ohms, hence the circuit alone used 15 h. p., which left 17 h. p. for three cars, the friction of belting, shafting, dynamo, etc. This gives an average of 5.66 h. p. as necessary for each car.

One of these cars was climbing a grade of 350 feet to the mile at the time of the tests, and it is safe to say that it was using one-half the power delivered to the cars. Each car can be run at the expense of 5 h. p. delivered at the engine after the power necessary to overcome the line resistance has been deducted.

A good Corliss engine will deliver 5 h. p. for one hour with the consumption of 15 lbs. of coal, so it will require for each car 300 lbs. of coal per day of 20 hours. At $3 per ton the fuel for each car will cost 45 cents per day. It will require a constant expenditure of 15 h. p. to send the current over the line, and this amount will not vary with the number of cars on the line. This will cost $1.50 per day for coal.

The conductor used in this city is too small, as it was intended for a 30 ampere current, and was not changed when the 40 amperes were adopted, so the loss on the conductor is abnormally large.

The economy of this series road can be realized better when compared with the same system of tracks and conductors where the cars are run in multiple arc.

Suppose the same conductors be arranged in parallel, and the cars placed in derived circuit upon them. The average resistance could then be reckoned as 3.5 ohms (as with all the cars are at the centre of the line), 40 amperes being required to run each motor.

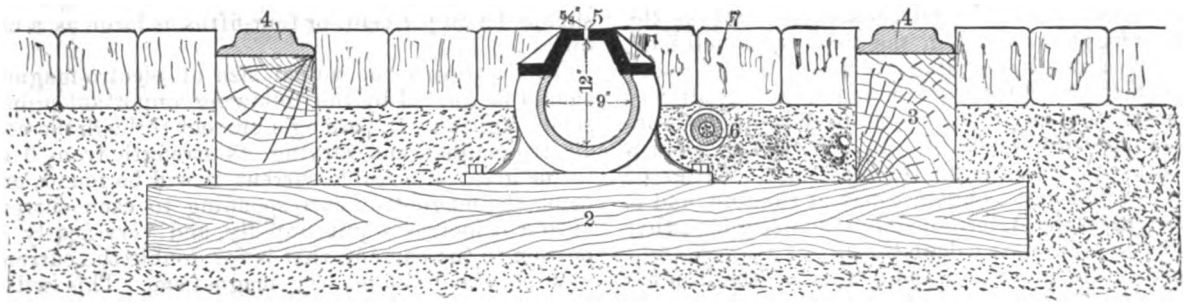

FIGURE 8.—SECTION OF ROAD-BED.

2, TIES; 3, STRINGS; 4, RAILS; 5, SLAT IN CONDUIT; 6, CABLES; 7, PAVEMENT.

Power required for	Multiple arc.	Series System.
1 car	12½ h. p.	20 h. p.
2 cars	40 "	25 "
5 "	212 "	40 "
10 "	800 "	65 "
20 "	3102 "	115 "
40 "	12210 "	215 "

It may seem unfair to compute the power necessary to run cars in multiple arc, using such small conductors as No. 3, but large conductors cost more, and the series road runs with great economy with the small conductor.

In the series road the larger the number of cars the less the percentage of loss or waste on the conductor, which is just the reverse of the multiple arc system. This seems to be the one thing which excludes the multiple arc system of electrical railway from large systems where a great number of cars are in operation.

The series system is the only one which is applicable to long lines of street cars where there are large numbers of cars in service. The results obtained in Denver prove that by using this series system, electricity becomes the cheapest motive power for street railways.

DYNAMIC ELECTRICITY.

BY CARL HERING.

CHAPTER VII.—FIELD MAGNET FRAMES.

THE general principles underlying the construction and designing of electro-magnets, have been given in chapters

Digitized by Google

iii and iv[1]. As the field magnets of a dynamo usually serve also as a frame work for the machine, their design and construction should be based on mechanical considerations as well as to meet the requirements of good magnets. For instance, it is well known that wrought-iron magnets of the same size as those of cast-iron are more powerful and more economical, but if the nature of the frame of the machine which constitutes these magnets be such as to increase the cost very greatly, it is evident that it will be more economical in such cases to use cast-iron and to make the magnets larger. A cast-iron magnet can in all cases be made to generate as strong and large a field as one of wrought-iron (though not of the same intensity per square inch) by simply making it as much larger as is required by its smaller capacity. The efficiency of the cast-iron magnets, that is, the amount of useful magnetism generated per watt of electrical energy in the coil, may not be as great as the efficiency of wrought-iron magnets, partly because they are not capable of carrying the same number of lines of force per square inch of cross-section, and partly because, being larger in diameter, the wire of the coil has greater length and resistance. But as the amount of energy consumed in the field is, in well built machines, only a small percentage, it would not add very much to the efficiency of the machine to reduce this already small percentage by employing the more efficient and more expensive wrought-iron magnets. In this, as well as in a number of other points, it is, therefore, a mere matter of choice between first cost as against cost of running, and it may in most cases be determined by the designer either by trial or by approximate calculations.

The general rule regarding the quality of the iron for the field magnets is to have it as pure and as soft as practicable, considering, as just described, both the first cost and the gain in the magnetic qualities. Wrought-iron which has been rolled, usually has a "grain" somewhat similar to that of wood, the fibres running in the direction of the length of the bar. Such iron magnetizes better in the direction of the fibre, than across the grain, and it is therefore preferable, wherever it is possible, to so place the iron that the lines of force run parallel to the grain. Wrought-iron in the form of fine wire or thin sheets may usually be relied upon as being soft, but in this form its use is limited to small machines and to armature cores.

When cast-iron is used it should be as soft and as free from impurities as possible. It is preferable whenever possible, to have it annealed, and when not too large in bulk, to have it converted into malleable iron; this is especially to be recommended for small machines and motors. Corners, projections, and thin edges should be avoided as much as possible on the castings as they are apt to chill while being cast, thus making them quite hard, and destroying their magnetic qualities. Corners and edges should be well rounded off, and whenever thin projecting edges are necessary for mechanical reasons they should be cast quite thick and massive, and may afterwards be planed or turned down if necessary. It is preferable to cast the iron in dry moulds and to allow it to cool as slowly as possible, preferably for three or four days in a gradually decreasing fire.

The cores of the magnets are usually the parts where the lines of force are most dense, as it is the smallest cross-section through which the magnetism has to pass. A very good and economical magnet can therefore be constructed by making these cores of wrought-iron and the pole pieces and yoke pieces of cast-iron.

The relative value of cast and wrought-iron magnets may be deduced from the following figures. Sylvanus Thompson states that cast-iron magnets will give about 60 per cent. of the effect of wrought-iron magnets of equal size. For instance, if a wrought-iron magnet can have 100,000 lines of force passing through every square inch of its cross-section of core, at saturation, a cast-iron one will have 60,000 at saturation; to be equal to the wrought-iron magnet it would have to be two-thirds again as large in cross-section of core, because every $1\frac{2}{3}$ square inches will then contain the same number of lines of force as one square inch of the wrought-iron core. A wrought-iron magnet, according to this statement, need be only 60 per cent. or three-fifths as large in cross-section as a cast-iron one equal to it in effect. The length of the core will depend in general only on the amount of wire which it is necessary to wind around it in order to generate this magnetic effect in the core.

Kapp[2] states that in two similar machines, differing only in having the field magnets of the one made of cast-iron and of the other of wrought-iron, the electromotive forces generated were 80 and 100 volts respectively. As all other conditions were the same, it follows that the result must be due solely to the magnetism, and that, therefore, the cast-iron has 80 per cent. of the effect of wrought-iron. According to this, a cast-iron core should be one-quarter or 25 per cent. larger in cross-section than an equivalent wrought-iron one, and *vice versa*, a wrought-iron one should be 80 per cent. or four-fifths as large as a cast-iron one.

To determine the actual size of electro-magnets, one should be guided by the following important property of such magnets. In passing a current through the coil of an electro-magnet, and varying its strength from 0 amperes to the greatest possible current, it will be found, on measuring the magnetism corresponding to each current, that at first it increases quite rapidly, and very nearly in proportion to the current, that is for double the current there will be about double the magnetism. This will be the case up to a certain point, when the conditions will suddenly change, and on increasing the current still more the magnetism will increase only very slightly. At this point, called the point of saturation, the action of the iron in adding its share to the magnetism, appears to cease; all the increase above this point appears to be that due to the current itself, as if the magnet were a mere solenoid, or coil without iron. Up to this point the magnetism is obtained cheaply and economically, but above this point the increase in magnetism is so small and requires such a large expenditure of current, electromotive force and wire, that it is prohibitive in well built and efficient machines. It is of very great importance, therefore, to guard against over-saturating to any great extent the magnets or any part of the magnetic circuit of the field magnet frames, as it will always be found that it takes less copper or less electrical energy, to generate the same amount of magnetism in a larger core which is not over-satuated than in a small over-saturated core. This is especially important in small or cheap machines, or in those in which there is a scant allowance of iron in the magnetic circuit. As the actual additional weight of iron required to bring the magnetization of an over-saturated magnet down to the saturation point, is so small, and therefore inexpensive, there is in general no reason why it should not be added. As iron itself appears to add to the lines of force which are due to the current alone, there is an additional advantage in using as much iron as possible, the magnetism of the iron itself requiring very little electrical energy to render it useful. When cast-iron magnets are used there is a still further advantage in using larger, massive magnets, as the iron is more apt to be cast soft than when they are small and thin. How to find out whether the magnets are over-saturated too much will be explained in a subsequent chapter. Some makers prefer to over-saturate the magnets to a slight extent because the field is then less sensitive to slight changes of the current in the coils; in other words, the machine is steadier in its action. If this is to be done it should be to a slight extent only. But as machines are generally regulated by altering the current in the field, it would seem that it is desirable to have the field

1. Electrician and Electrical Engineer, June and August, 1886.

2. *Electrician*, London, May 22, 1885, p. 23.

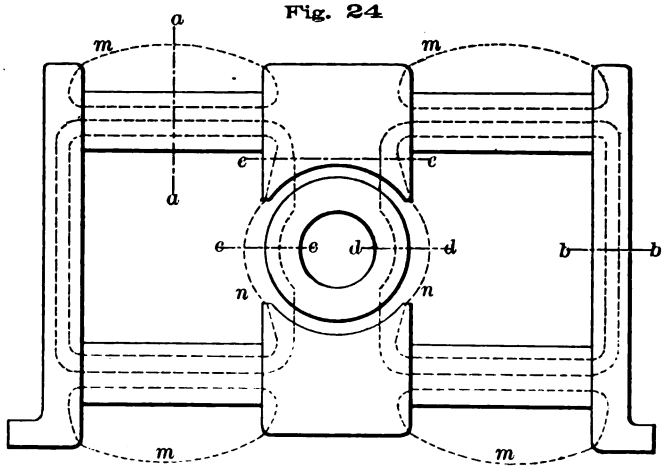
Digitized by Google

as sensitive to variations of current as possible, in order that it shall require less variation of this adjusting or regulating current.

Scientists have up to the present time failed to give the dynamo builder any practical and reliable data and rules by means of which the actual sizes of the parts of a field magnet frame may be determined with any degree of certainty from the intensity and size of the field required by the armature. In the absence of this greatly needed information, the designer of dynamos will have to use his judgment, if he has no access to a finished model machine, from which to obtain the desired data. The following relations may be used as a guide in determining the approximate sizes.

Every line of force must make a complete closed circuit around its exciting current, as explained in chapter iii. For instance, in the well-known form of magnet frame shown in figure 24, the lines of force will pass through the

Fig. 24



iron as shown in dotted lines, the only portion of them which is rendered useful, that is, which may be cut by the armature wire, is that passing from the pole pieces through the air space to the armature and out at the other pole piece. Iron is saturated when a certain number of lines of force pass through every square inch of its cross-section; if, therefore, the iron was of the same quality throughout, and if these useful lines of force were the only ones, it is readily seen that the cross-section of the yoke piece at *b b*, should be at least equal to that of the core at *a a;* the cross-section of the pole piece at *e e*, should be at least twice that at *a a*, as it contains the lines of force from both halves of the frame, as seen from the dotted lines. If a Gramme ring armature is used, the lines of force divide equally, half of them going through each half of the ring; its cross-section *c c* = *d d*, ought, therefore, to be equal to *a a;* if it is a cylinder armature the whole cross-section *c c d d* should be equal to twice *a a*. As the lines of force generated in the magnet *a a*, return through the other core below it, it follows that in such a frame each core must be made large enough to contain all the lines of force generated in it and in the other core belonging to that pair, considering them as the two parts of a U magnet. In other forms of frames, it may be readily determined what the relative cross-sections should be, by merely following the lines of force throughout their circuit and giving each line of force the same area of iron to pass through. For instance, in the Edison form, one pair of cores take the place of the two pair in figure 24, and should therefore be twice as large in cross-section.

Referring to figure 24, it will be noticed that a few of the lines of force, as *m*, *m*, *n*, *n*, do not pass through the armature and are therefore lost, representing so much leakage, as it might be called. But as these all pass through the cores of the magnets, allowance should be made for them in the cross-section of these cores and they should therefore be larger in comparison to the core of the armature, than if there was no leakage, as was supposed in the above mentioned rule. It is not possible to state just how much to allow for this leakage, as it depends greatly on the detailed parts. For rough calculations it might be estimated that in the forms shown in figure 24, about one-quarter of the total number of lines of force are lost by this leakage, in which case the cross-section at *a a*, should be one-third again as large as that at *c c*.

The iron of the armature is generally of much finer quality than that of the field magnets, and therefore its cross-section per line of force may be made smaller. Taking the results of Kapp's experiments for wrought and cast-iron given above, it would follow that the cross-section of a wrought-iron armature may be made 60% of that of a corresponding cross-section of a cast-iron magnet core. This would still further increase the cross-section at *a a*, figure 24, over that at *c c*. On the other hand the cross-section of the armature core, which ought to be laminated, is not entirely composed of iron; allowance should therefore be made for the spaces occupied by the insulating layers, or the air ventilation space.

There is no objection to making the cross-sections at any point larger than that which would be required by the rules just given, provided it does not uselessly increase the length of wire on the coils or armature. The important point is that they should not be smaller than that required by these rules. For instance, the yoke piece at *b b*, or the pole piece at *e e* may be made as much greater as is desired, the effect will even be advantageous, as it adds to the number of lines of force inherent in the iron. The two places where there should be no more iron than is absolutely necessary are the cross-sections of the cores *a a*, and that of the armature *c c*. The latter, however, may be limited by the nature of the armature and its winding, and for cylinder armatures it may often have to be greater than that required by the number of lines of force; in Gramme armatures, on the other hand, it is often much too small for the passage of the required number of lines of force and is therefore saturated long before the field magnets are at their maximum intensity; this causes neutralizing reverse currents in the inside wires, great leakage of otherwise useful lines of force, and consequent bad sparking in the otherwise dead or short circuited coils in the neutral field. The objection to increasing the cross-section of the cores at *a a*, above what is absolutely necessary is, that it increases uselessly the length of the wire of the coils, which in well built machines is an important item in the cost of the material for a machine.

The armature current itself generates quite a number of lines of force in its core. These partly leak through the air and return to the other side of the core, but most of them return through the frame of the field magnets together with the other lines of force and in the same direction. They therefore help to saturate the iron. If this counter-magnetization of the armature is small, as it should be in well built machines, the effect will not be great; but in armatures with many turns of wire the effect is not small and should be allowed for by an additional increase in the cross-section of the iron.

In the foregoing chapters it was shown how the number of lines of force required by the armature may be calculated approximately. If it were known how many lines of force could be generated per square inch of cross-section of magnet core for different qualities of iron, and if it were known how many of the lines of force were wasted by leakage, it would be very easy to calculate the necessary cross-section of the field cores. No complete and reliable set of such figures have been published, but the following may serve as a rough guide. Kapp[3] states that in wrought-iron field magnets of hammered scrap, 108,000

3. Proceedings of Society of Telegraph Engineers, Nov. 11, 1886,—"Characteristics of Dynamos."

Digitized by Google

lines of force may be passed per square inch of cross-section; in armatures of charcoal-iron, well annealed, 150,000, and of discs of similar iron, 132,000. Fleming states that in a long magnet of soft annealed iron, the greatest strength is 116,000 lines of force per square inch. The same authority states that in the best dynamo the intensity of magnetization is from about 40,000 to 65,000 lines of force per square inch, by which we suppose he refere to the magnet cores and not to the armature field. In the Edison and Weston machines, tested by the Franklin Institute, a rough estimate gives about 70,000 to 90,000 in the cores.

If a suitable machine of a similar style to the one to be constructed, is at the disposal of the designer, it is very easy to determine from it, as follows, what the cross-section of the cores should be for a larger or smaller machine of the same general type, or of one differing only in the armature. Run the machine with a separate exciter and without a current in the armature; measure the potential on open circuit for gradually increasing exciting currents. When the increase in potential begins to be much slower than the increase in the exciting current the machine is saturated. With this intensity of field at saturation, let the armature current flow through its proper external circuit and measure its current and potential. From this and the detail dimensions of the armature the number of lines of force in the field can be calculated as described in the previous chapters. Knowing the intensity of field required by a new armature for another machine it is only necessary to increase or diminish the cross-section of the magnet cores in the same proportion as the new field is larger or smaller than the one tested.

The length of a magnet core depends only on the amount of wire which is required in its coil to generate the necessary number of lines of force. It is evident that it takes a certain number of ampere turns to develop the required magnetism, and owing to the limited resistance of these coils and to their allowable degree of heating, the amount of wire is also limited. If the coils are very short, the thickness of the coil will be so great that the outside layers may not have their full effect, being too far from the iron; it will also make the outside layers unnecessarily long. On the other hand, if the magnet core is very long, the thickness of the coil will be very small, which by itself is an advantage, but the weight of iron will then be uselessly great, making the machine larger and heavier than is necessary, while the greater magnetic resistance and the greater length of the course of the lines of force will both tend to weaken the magnetic strength and to increase the leakage.

One of the older authorities states that the best relation between the coil and core of a circular magnet is when the core is one-third of the whole external diameter of the magnet, that is, when the thickness or depth of the coil is equal to the diameter of the core. But although this may be the case for telegraph magnets, it is certainly not the case with dynamos, in which the cost of the wire and the resistance of it are of much greater importance than in telegraph magnets. A very good rule, and one which is based on actual experience with machines, as distinguished from theoretical deductions, is to make the thickness or the depth of the coil about one-third of the diameter of the core on round magnets, and one-third of the smaller diameter on oval magnets. If made much greater than this the magnets will be apt to heat too much, or to over-saturate the core, or to have a uselessly large amount of wire on them. If much less than this, it will generally be found that the magnets are larger than would be necessary to answer the purpose. This latter is no serious fault and will not, as in the other case, prevent the magnets from generating at least the desired amount of magnetism, and on the contrary will allow for an increase of magnetism if it should be found necessary; it is, therefore, much safer to make the cores thicker and longer, and consequently the depth of the coil less, than what might at first appear to be necessary. Furthermore, in many forms of frames, the cores can readily be shortened if it should be found necessary, while they cannot always, so conveniently, be lengthened.

If the number of ampere turns required for a magnet were known, it would not be difficult to determine the length of the core, because, its cross-section can be determined as described, from which together with the ampere turns and the allowable thickness of coil, the length is readily calculated. But in most cases the ampere turns are the last thing to be determined, when the machine is otherwise completed, and it, therefore, remains only for the designer to use his judgment regarding the length which the cores should have. Besides the remarks already made concerning the length of cores, the following may be used as general guides. Deprez states that to have the best effect the length of a magnet should not be greater than three times its thickness; this we presume refers to the core and not to the outside dimensions of the whole magnet with coil. A short thick magnet will magnetize and demagnetize more readily, or as Fleming states it, "such a magnet has no magnetic memory;" it responds more quickly to changes of current in its coils. Some makers consider this a disadvantage and purposely over-saturate their magnets in order to "steady" them in their action. The tendency of reliable and systematic dynamo builders has been toward short thick magnets and it may, therefore, be accepted as a safe example to follow.

The following general principles governing the magnetism of coils may also serve as a general guide in designing magnets. In a circular coil of wire composed of a turn or turns of wire, as for instance in a large tangent galvanometer, if the radius in centimeters is r and the ampere-turns are represented by c then the intensity of magnetism at the centre, in lines of force per square centimeter, will be

$$i = \frac{2\pi c}{10r}$$

which may be reduced to

$$i = .6283\frac{c}{r}$$

or if d is the diameter,

$$i = 1.25664\frac{c}{d}$$

Or if R and D are the radius and diameter in inches, and I the intensity in lines of force per square inch, these formulæ become

$$I = 1.5959\frac{c}{R} = 3.1918\frac{c}{D}$$

In these formulæ c will be the current in amperes if there is only one turn in the coil, but if there are many turns c is the current multiplied by the number of turns, that is, the ampere turns. From these formulæ either the intensity, diameter or ampere turns may be calculated.

According to a statement made by Clerk Maxwell, the intensity in all points in the interior of such a ring or coil and in the plane of the ring, is equal. It follows from this that the number of lines of force enclosed in the ring is equal to the intensity multiplied by its area. Hence if M is the total number of lines of force in this coil it will be equal to

$$M = i\,\pi\,r^2 = 1.9739\,c\,r = .98695\,c\,d$$

or, if the dimensions are in inches,

$$M = 5.0137\,c\,R = 2.5069\,c\,D$$

When the coil is oval or any other form of cross-section, it will in most cases be sufficiently accurate to use for the diameter or radius that of a circle whose area is equivalent to the oval.

Many deductions can be made from these formulæ, some of which may serve as guides in constructing magnets. For instance, it will be seen that if the diameter of the

Digitized by Google

coil is doubled, the magnetic intensity, for the same current, will be halved, but as the area is four times as great the total magnetism will be twice as great; the wire being twice as long, the electrical energy required to develop this magnetism will be twice as great if the wire has the same diameter; if the cross-section of the wire is also doubled (or its diameter made 1.4 times as great) the resistance will be the same, and therefore the energy required will be the same, notwithstanding that the magnetism has been doubled. This shows that the amount of magnetism does not depend on the amount of electrical energy or watts in the coils; any amount of magnetism may be developed with even a very small number of watts, if the resistance could be made low enough. The amount of magnetism depends only on the current and the distance through which this current passes, or on what might be termed the ampere feet or ampere yards. With a wire of low enough resistance the distance or length, and therefore the magnetism, may evidently be made very great for even a small number of watts.

These formulæ are correct only for a coil in which the amount of wire is very small. For a long or thick coil they will not be strictly correct, but they may serve as a general guide in calculating larger coils from the effects of smaller ones, or the reverse. In general, they may be relied upon for relative proportions between two magnets.

When iron is introduced into the coil, as in an ordinary electro-magnet, the intensity and total number of lines of force will be increased greatly. The iron acts as if it contained a large amount of magnetism in it, which was rendered active by passing a current of electricity near it. Its action may be pictured as follows: suppose a quantity of steel filings were magnetized very strongly and placed in a round bottle containing thick syrup or any other material which will suspend them but which will not allow them to turn around unless some force is exerted on the particles of steel. Each piece representing an enlarged molecule of iron, being a magnet, will attach itself to others of opposite polarity, thus forming complete little magnetic circuits amongst themselves. If well shaken they will attach themselves as described and will therefore exhibit no definite polarity to a needle placed outside, though they will attract the needle. This represents iron in its normal condition. If a coil be wound around this bottle and a current be passed through it, these little magnets will turn on their axis and arrange themselves perpendicular to the wire of the coil and parallel to the lines of force generated by the current. They will therefore, each add their magnetic intensity to that of the current, as they have arranged themselves in the same direction. They will then exhibit polarity to a needle outside of the bottle, the polarity being the same as that of the coil. The stronger the current the greater will be the force to turn their particles out of their normal position and into that induced by the coil. Their external magnetism will therefore increase with the current until they have all been turned parallel to each other, the increase of magnetism of the particles will then stop. This corresponds to the point of saturation above which the magnetism of the iron itself cannot be increased. When the current is stopped they will again attach themselves to each other forming closed magnetic circuits, and not showing any external magnetism.

(*To be continued.*)

NOTE ON THE PERFORMANCE OF SOME DYNAMOS.

BY D. C. JACKSON.

THE following table was constructed with a view of comparing the results attained by the several prominent dynamo builders, principally English and American. The data were gathered wherever obtainable and reduced to uniformity. In most cases the authority for the original figures is given in the last column. Where this is omitted the results were gathered from measurements made on machines in the physical laboratory of Cornell University.

The importance to designers and those engaged in the study of the performance of dynamos of such a table, is thought to be sufficient apology for its publication.

The first three columns of the table explain themselves. In the column marked velocities, are given periphery velocities in feet per minute.

The columns marked I, II, and III, contain respectively the E. M. F. in volts generated by the machines per foot of armature wire, volts per foot of wire and per unit periphery velocity (1 ft. per sec.), and volts per foot of wire and per one revolution per minute.

The dynamo with Siemens armature called "2½ inch" is a little machine with armature about 2½ inches in diameter and six inches long. It is one of two such machines built by Prof. Anthony for experimental purposes. The excellent performance of so small a machine is explained by the excellence of its construction. Its field magnets are solid forgings of Swedish wrought

Digitized by Google

iron and the armature core consists of thin insulated plates of soft iron.

The "old Gramme" dynamo was built in the laboratory in 1874, by Prof. Anthony, immediately on learning of Gramme's success. It has been in constant use ever since for experimental purposes in the laboratory. Its field magnets have wrought iron limbs and cast iron pole pieces and end yokes. A comparison of its performance with that of the Raffard-Breguet, one of the latest French dynamos, is instructive.

The machine of Deprez given in the table is the generator in the final Paris-Creil experiments.

CORNELL UNIVERSITY,

ABSTRACTS AND EXTRACTS.

THE TELEPHONE SERVICE CABLE SYSTEM AT COPENHAGEN, DENMARK.

THROUGH the kindness of Mr. F. R. Welles, of Antwerp, we are enabled to publish the following information in respect to the introduction of cables for telephone service, from a recent letter of Mr. C. L. Madsen, of Copenhagen, placed at our disposal by Mr. Welles.

"The cable system in the telephone establishment in Copenhagen, was opened for service in the month of November, 1885.

The underground cables extend in a continuous line from the middle of the city to a point on the western boundary, from which they spread in southerly and northerly directions. By means of the underground cables and adjoining aerial cables and pole lines all the central offices in Copenhagen, exchanges, at present six in number, the central office for the public stations, at present 24, and several other important points are provided with a large number of permanent trunk wires, and in this manner, put in direct communication with each other; thus, never more than two central offices are required for connecting up any two subscribers.

Between the two large central offices in the town (I. and II.) and including the Royal central station, eight cables are laid. From the western central bureau (II.) to the junction named above, three cables are laid, and from this point the cables are spread as described.

The total length of all the cables amounts at present to 28 kilometers, out of which 19.5 kilometers belong to the underground system, 7.3 to aerial cables and the remainder, 1.2 kilometers, to submarine cables, crossing the harbor. The total length of all the cable wires is about 800 kilometers, and the total length of all the wires in the entire system amounts at present to more than 3000 kilometers. The telephone establishment in Copenhagen serves at present about 1500 subscribers.

All the underground and aerial cables named above belong to the class of anti-induction cables, which are delivered by Messrs. Felten and Guilleaume from their works, "Carlswerk" at Mulheim on the Rhine; the cables were designed by that firm in conjunction with myself expressly for the purpose of working all the conductors on the single wire principle. The work done is, in fact, the realization of the views and plans laid down in a treatise on "Telephone Establishments in Large Cities," which I published early in 1885. From the following you will see how perfect this extensive cable system has worked ever since it was laid.

In respect to details of construction of the cables the following points may be of special interest.

1. *Underground cables.* Of these two types of cable are used. (*a*), In short lengths for distances up to three kilometers the cable is composed of 27 copper conductors, each 0.8 mm. diameter, insulated according to Messrs. Felten and Guilleaume's patent to 2.1 mm. diameter; (*b*), in long lengths for distances up to six kilometers, the cable consists of 27 copper conductors, each 1.0 mm. diameter, insulated as above to 3.0 mm. diameter.

In both of the above types all the cores are covered with a layer of tinfoil; three naked copper wires are placed in the middle of the cable to serve for the earth connection. The whole of the cable is laid up as usual, served with an insulating ribbon and thereafter with a double cover of lead, laid on under hydraulic pressure. The cable is finally protected outside with an asphalted tape.

On an average the copper resistance of the above cables is found to be respectively 35.6 and 19.2 ohms per kilometer, the insulation about 500 to 1500 megohms per kilometer and the inductive capacity about 0.19 to 0.13 microfarads per kilometer.

2. *Aerial cables.* These cables are constructed on the same principle as the underground cables only that the cable contains 26 copper wires 0.8 mm. insulated to 1.8 mm. The cable is provided with a carrying strand consisting of 19 steel wires 0.8 mm., which at the same time serves for the earth connection. The outer protection is made fire proof and painted white.

3. *Submarine cables* are made of 30 G. P. wires laid up in the usual manner and protected with the required armor of heavy iron wires, covered with an outer compound.

After having been laid the whole cable system has been continually tested with the result that all the conductors up to date have been found in perfect electrical condition and in perfect working order. For the purpose of testing the cables and other conductors in the telephone system, a very complete testing room has been erected at the central station "Royal," in which all the wires from the 16 cables (eight to each of the two central offices I. and II.), are joined up in testing boxes, provided with binding screws and affording free and easy access to each wire.

The telephone system of Copenhagen reaches as far north as to Elsinore at the Sound, about 60 kilometers; southwards to Kjóge, about 40 kilometers; and westwards to Roskilde, about 35 kilometers. The greatest distance over which speaking is carried on is, therefore, about 100 kilometers, Elsinore—Kjóge. In this circuit is employed a total length of about eight kilometers of cable wire. Other circuits comprise up to about 70 kilometers of wire, including about 10 kilometers cable wire.

In connection with the cable system several contrivances have been employed. Of such I may name, that the earth wires in the underground cables are connected with the earth at different intermediate points along the route; this arrangement is made in order to accelerate the discharge of the cables, but the effect of this device has still to be more accurately ascertained. Another and most effective arrangement is the shunting of all the annunciator coils; by experiments the best resistance of the shunt coils was found to be four to five times that of the annunciator coils, or about 600 ohms against 120. At this ratio the drops work well, and at the same time the influence of the shunts on the talking was very remarkable, so that the speaking through the described circuits could be carried on with perfect ease.

The cable system has improved in a remarkable degree the permanency and stability of all the conductors and communications; the interruptions and derangements, frequently caused by storms and accidents, have considerably decreased in number and import since the long trunk lines have been placed underground. There is no doubt that in this respect cables would afford many advantages when laid in intermediate places, where long spans or want of free line and proper supports threaten the continuity of important parts of the circuits."

THE VERIFICATION OF FARADAY'S LAW OF ELECTROLYSIS WITH REFERENCE TO SILVER AND COPPER.[1]

BY W. N. SHAW, M. A.

SINCE the time of Faraday his law of electrolysis has not been

1. Paper contributed to the British Association Meeting, 1886.

Digitized by Google

subjected to any very extensive experimental investigations. A summary of the results obtained is given in the article on electrolysis in the "Encyclopædia Britannica." The most accurate verification appears to have been conducted by Soret, who attributes to the law an accuracy of 0.2 per cent. for copper and silver. Buff used different currents, and found the law verified by experiment to about one per cent., but the general impression has been that the law was only true to a somewhat rough approximation.

A practical acquaintance with the behavior of an electrolytic cell of copper sulphate shows that it is not *necessary* to attribute the defect from the theoretical value of the chemical equivalent obtained in that way to the failure of Faraday's law. In depositing copper upon a copper plate it may often be observed that small but brilliant red crystals are formed on the deposit. These crystals under the microscope are very beautiful; they may probably be regarded as a suboxide of copper formed by the action of the copper on the solution. A purple coloration is, moreover, often formed on the cathode, and this is possibly due to the presence of the same compound of copper. This secondary action produces, of course, a difference in the weight of the deposit formed, and the true amount of electricity which has passed cannot be inferred either from the weight of the copper with the compound or from the weight of copper remaining when the crystals have been removed.

Further, it is well known that a copper plate when immersed in a solution of copper sulphate without any current gives rise to some chemical action which causes the copper plate to alter in weight. The alteration may be either in the direction of increase or of decrease of the weight, the effect depending upon the state of the plate and the state of the solution.

In considering the increase in weight of a copper cathode in an electrolytic cell we cannot without definite experimental reasons neglect to consider the possibility of both these actions occurring together, and, moreover, the passage of the current may produce complicated results which cannot be inferred from the action of the solution in the cell under other conditions. Dr. Gore has made very numerous experiments upon this subject, without, however, arriving at any very satisfactory result.

In view of the importance of the subject, a very large number of experiments have been made at the Cavendish laboratory at Cambridge under my direction during the past two years. They may be divided into two groups: (A), experiments to ascertain whether two copper cells give the same amount of deposit for the same current; and (B), experiments to determine whether a copper cell can be arranged so that, on comparison with a silver cell, within sufficiently wide limits of current it will give a value of the chemical equivalent of copper agreeing with that obtained by chemical methods.

A.—EXPERIMENTS ON COPPER CELLS ONLY.

These experiments consisted in arranging pairs of copper cells with various electrodes, as copper plates, copper wire, copper cylinders having wire connections, platinum wires, in order to ascertain whether the disturbing actions were limited to the surface. The results were very irregular and disappointing. Errors amounting frequently to more than one per cent. occurred without any assignable cause.

The same is all that can be said about experiments with different solutions of sulphate, including solutions from which air had been expelled by boiling, the experiments being then conducted under the receiver of an air pump. Endeavors to allow for the differences for the cathode weighings by supplementary experiments on the effect of the solution upon plates not connected with the electrodes have likewise proved fruitless. The enumeration of these experiments would serve no practical purpose, as they lead to no generalization; I shall, therefore, pass over them.

B.—EXPERIMENTS ON THE COMPARISON OF SILVER AND COPPER CELLS.

One of the most disagreeable features of the experiments referred to in the preceding section was that when two cells were compared, and a difference in the increase of weight of the cathodes was obtained, it was impossible to say whether either or both of the two cells was at fault, and it was therefore decided to employ a silver cell as a standard. Lord Rayleigh was at the time engaged on his experiments upon absolute value of the electro-chemical equivalent of silver, and had not yet arrived at a result. Experiments were therefore made to obtain a silver cell that might be fairly regarded as a standard. The only difficulty in the way was that the deposit of silver from pure nitrate is crystalline and very rough. The deposit was taken upon a platinum crucible, and it was feared that error might arise, either from mechanical loss of the silver during the operation of drying, or from the retention by the deposit of water, or salt in solution. Attempts were therefore made to use as electrolyte (1), a solution of chloride of silver in hypo-sulphite of silver (2), a solution of nitrate of silver containing glycerine (3), a solution of nitrate of silver containing acetate of silver. The deposits obtained with all these are much closer and harder, but the hyposulphite solution is very unstable, and a current beyond a certain density precipitates a black sulphide which destroys the experiment. The other solutions were also discarded after consultation with Lord Rayleigh, who had then shown that a 15 per cent. solution of pure nitrate gave a perfectly satisfactory silver cell if proper precautions were taken with the drying, whereas the solutions containing organic salts were liable to serious error, probably in consequence of the inclusion of the solution in the pores of the deposit.

It was originally intended to use only those experiments from which the loss of the anode was obtained equal to the gain of the cathode. It was found, however, that the possibility of weighing the loss of the anode was simply fortuitous, the action of the solution upon the silver always producing a sort of honeycomb formation, and ultimately leaving smaller particles which fell off in washing. This was the case even when a silver crucible was used as the anode. It was therefore decided to use the gain of the cathode only. The form of silver cell adopted is that of Poggendorff's voltameter, in which a platinum crucible standing on a copper plate is the cathode and a silver rod the anode. The crucibles were about 1½ inches in diameter and two inches high, and the silver rod forming the anode was about half an inch in diameter.

The method of drying the deposit was to wash in distilled water by filling up the crucible several times, and allowing it to stand for some time, then, after thoroughly rinsing, to wash it out with alcohol and dry in a hot air bath at about 260° C.

As the crucibles were very different in size from those used by Lord Rayleigh some experiments were made to determine their behavior.

The results are shown in comparisons (A), (B), (C), (D), given below.

" 7	130	.2852	2.4901	2.4900	.0001

The chlorate deposit after being heated to redness was dissolved in pure nitric acid and the solution tested for chloride, but none was found.

The silver cell being thus shown to be capable of working quite satisfactorily, the arrangement and comparison of copper cells were proceeded with. It was found in the previous experiments on copper that the deposits obtained on platinum wires gave much more concordant results than any other form of cell. This form of cell had been already used by Soret. It was accordingly decided to adopt that form. The cathodes were platinum wires about 15cm. long and 1mm. in diameter, and the anodes were wires of electrolytic copper whose diameter was somewhat greater. It is, however, well known that the density of the solution alters very considerably in the neighborhood of the cathode, and if the electrodes are vertical this effect is not so much interfered with by convection currents as when the electrodes are horizontal. The wires were therefore placed horizontally in the solution; for this purpose they were bent at right angles, and the one end fastened to a binding screw attached to a thick wooden rod that lay on the edges of a porcelain dish that contained the electrolyte. A number of cells were prepared respectively for 1, 2, 3. .....up to 16 wires. The wires were arranged about two inches apart, and between them lay the anode wires attached to a similar piece of

Digitized by Google

wood that rested on the other end of the dish; the wires in the same cell were put in multiple arc by a strip of copper laid along the wood, through which the binding screws passed. Some difficulty was met with in arranging that the anodes and cathodes did not touch, but with care it was surmounted. The solution was an approximately saturated solution of Hopkin and Williams' pure copper sulphate. No acid was added. The wires with their deposits were washed by rinsing them in several changes of distilled water and then dipped in alcohol and dried in an air bath at a temperature of about 100° C.

In the experiments given below the copper deposits were brilliantly clean and generally showed no trace of oxidation on drying. The reason for this was never made clear; it is, however, easily recognized that under certain circumstances, defined perhaps by current density or the state of the solution, the copper deposits do not easily oxidize on drying, whereas in other experiments it seems almost impossible to dry them without considerable oxidation.

In all the experiments a rough tangent galvanometer was included in the circuit, so that any considerable variations of the current might be detected. A water or dilute copper sulphate cell, with copper electrodes whose distance apart could be adjusted, was also included to serve the purpose of a rheostat.

In a first series of experiments a silver cell was compared with each one of the copper wire cells in turn; the results are given in the table i.

* Discarded.

It will be seen that the extreme error of the values from the mean amounts to rather less than one-half per cent.; the errors are irregular, but the difficulty of keeping the current constant was very great, and in some cases there was considerable difference, so that no inferences as to the effect of current density could be drawn. The arrangement was therefore altered, and five copper cells containing respectively 1, 2, 4, 8, and 16 wires, were all included in the same circuit with one silver cell. The electromotive force was obtained from 12 storage cells, or from Grove's cells. The observations are included in the first part of table ii. There was still some difficulty in keeping the current constant, and the apparatus was in consequence transferred to Emmanuel College, where a dynamo working at 110 volts for electric lighting was available; a satisfactory series of observations was obtained, shown in the latter part of table ii.

DISCUSSION OF THE OBSERVATIONS.

The numbers quoted in the table give the ratios of the amounts of silver to the corresponding amounts of copper deposited to the 4th significant figure. The balance used was a triangular beam Oertling, which could be relied upon for an accuracy reaching 0.1 mgm. The copper deposits generally amounted to about one gramme, and the accuracy of the weighings (corrected when necessary for the differences in the buoyancy of the air at the times of the initial and final determination of the weights) may be assigned as .01 per cent. for copper deposits, and .003 per cent. for silver. The numbers in the table are carried to one place less than the weighings permit. This is done intentionally in order to enable the reader to obtain a better general idea of the whole series of observations. It is easily seen that the differences in the table are real differences, and correspond to some real characteristic of the electrolytic action in the cells. A glance at the sets of observations belonging to the same experiment is sufficient to suggest a diminution of the amount of copper deposited as the current density diminishes. The area of each wire was about five square centimeters, so that the current density varies for the observations in table ii. between .001 and .15 ampere per square centimeter, and practically includes all current densities that can come under observation with this form of cell. In some cases the density was so great in the "one wire cell" that the copper deposit was flocculent, and could not be weighed in consequence; and in some of the 16 wires the deposit was not sufficient to cover the wires, but occurred in patches with small groups of copper masses.

If we proceed, on the assumption of the accuracy of Faraday's law, to attempt to explain the observed differences, we must first look to the action of the solution upon the deposit, since it is known that such an action actually takes place when copper is immersed in a solution of sulphate, and that the weight of copper might be reduced by solution. This action is said to depend upon the solution and the temperature. These considerations make it difficult to infer the action in the cell from that upon a wire without a current flowing: for, in the first place, the solution is weakened in the immediate neighborhood of the cathode by the electrolysis; and, in the second place, the temperature is altered by the current itself, and was sensibly different in the different cells in some of the experiments; but to measure the temperature and allow for it is not very practicable, as it is not uniform throughout the cell.

Further, there may possibly be a division of the current between the salt and the solvent, and any action of the kind would probably have an effect upon the action of the solution on the cathode.

The only plan that has suggested itself to me is to arrange the observations in the order of current density, and to see if any correction could be applied that would make the observations fairly comparable. This may fairly be applied, since the disturbing causes I have mentioned depend upon the current density.

In order to put this to the test, I have assumed in the first place that the action upon the deposit may be represented by an expression of the same form as would be required to represent the action of the solvent upon a wire immersed in the solution without any current. This we may take to be (for the comparatively short times of the experiments) a case of solution going in at a constant rate, and proportional to the area exposed. Thus, if δ be the actual loss of copper in an experiment when the area exposed is A, and the time t, we shall take

$$\delta = kAt,$$

and shall investigate whether a constant value of k can be taken to bring the observations into agreement. It is easily seen that this is equivalent to $\frac{\delta}{c} = \frac{k'}{d}$ where c is the total amount of copper deposited during the experiment, and δ the current density; and where k' is also constant, but numerically different from k. In words we may express this by saying that the fractional correction is inversely proportional to the current density.

LAW OF VARIATION OF THE DEPOSIT WITH CURRENT DENSITY.

It is difficult to settle what value to assume for k'. If k' be a true constant, its value can of course be calculated from any pair of observed results; but the magnitude of possible experimental errors, in comparison with that of the quantity under consideration, makes it highly improbable that the results would be at all concordant. It will at any rate be well, in order to avoid a possible error in the weighing of the silver, to use observations belonging to the same experiment for determining the value of k'. I have determined the values of k' for several pairs of observations, taken somewhat at random, with the following results (table iii.):—

TABLE III.

Experiment.	Range of current density.	k'
Oct. 10	.0014 — .023	.0000052
" 20	.0017 — .026	.000025
" 26	.0037 — .015	.000014
" 29	.0045 — .036	.000024
Dec. 15	.0077 — .031	.000025
" 16	.0115 — .092	.000017
" 17	.0063 — .051	.000017

The values of k' thus obtained are not very concordant. It must, however, be remembered that it is difficult to assign with confidence a numerical value to the current density, since the effective area of the copper surface may be practically very different from that of the platinum on which the copper is deposited. In the expectation that the action of the solution upon the copper when no current is flowing might help to decide which value of k' to take, the "one wire" and "16 wires" of October 20th were replaced in the solution, after the weighing was completed, and remained there for the time of duration of the experiment, viz., five hours. The "one wire" lost .0008 gm., and the "16 wires," .0110 gm. This gives a loss of .0007 gm. per wire, and corresponds to a value of $k' = .000025$. On November 27th, a loose copper wire was left in each of the cells during the experiment; and the mean loss of each of the wires during the time was .0003 gm., which corresponds to approximately the same value. It will therefore be well to see what effect the correction of the weighings on the hypothesis that $k' = .000025$ would have upon the tabulated results. The correction may be introduced by adding .00014 gm. to the weight of each wire immersed for each hour during which the experiment lasts. The following table shows the weights of copper as thus corrected (table iv.):—

TABLE IV.

Date.	1 wire.	2 wires.	4 wires.	8 wires.	16 wires.	Mean.	Mean per centage.
Oct. 10	.2855	.2853	.2853	.2869	.2889	.2864	0.4
" 20	.7952	.7942	.7941	.7957	.7949	.7948	0.06
" 26	.9932	.9922	.9931	.9934	.9950	.9934	0.06
" 29	.8519	.8516	.8520	—	.8518	.8518	0.02
Nov. 27	1.1498	1.1490	1.1489	—	—	1.1492	0.04
Dec. 15	1.4708	1.4700	1.4703	1.4704	1.4698	1.4703	0.02
" 16	1.1888	1.1882	1.1892	1.1894	1.1932	1.1898	0.11
" 17	—	1.2049	1.2043	1.2037	1.2048	1.2042	0.03
" 18	—	1.5172	1.5183	—	1.5215	1.5190	0.11

An examination of this table shows that, with some few exceptions, the results, as corrected, are very fairly concordant. That no value of k' could be found which would apply equally to all the observations is obvious from the discordance in the values of a k' tabulated above. A striking feature of the table is that the numbers under the heading of "2 wires" seem now to be the minimum values of the table; the "1 wire" values are all greater; and the numbers in the other columns are very rarely less, and then only by very small quantities. This shows that the correction applied is probably too large, though it is sometimes very successful. It is probable that the correction ought not to be applied when the current density is very great, as the difference between the "1 wire" and "2 wires" is increased by the correction, though not entirely due to it. This, as already pointed out, is probably *à priori*, since the more rapid deposition of copper would weaken the solution in the immediate neighborhood of the cathode. The correction may, however, be fairly adopted for the smaller current densities. It appears on examination of the current densities that the exceptional cases do not arise when the current density is below .02 ampere per square centimeter, so that the weights of copper deposited with currents of density less than .02 ampere per square centimeter, may be corrected by multiplication by a factor $1 + \frac{k'}{d}$, where d is the current density, and k' a constant not differing much from .00002.[1]

1. The values obtained by Lord Rayleigh with copper bowls (*Phil. Tr.* Pt. I. 1884, p. 458) are :—

CHEMICAL EQUIVALENT OF COPPER.

We have now to compare the results obtained for the ratio of the chemical equivalent of silver to that of copper with those obtained by purely chemical methods, in order to ascertain whether or not Faraday's law is strictly applicable in the case of silver and copper. If we take the results given in Landolt and Börnstein's "Physikalisch-Chemische Tabellen," we find the atomic weight of silver given as 107.66 by Meyer, and 107.675 by Clarke, and the accuracy is stated as being within .05; that of copper is quoted as 63.18 from Meyer, and 63.17 from Clarke, with a possible error of ± .5. This would give a value for the ratio of the chemical equivalents of silver and copper equal to 3.4086; or, allowing the fullest margin for error, the value lies between 3.38 and 3.44; so that the values obtained by the deposition of silver and copper seem to be all within the limits of error thus assigned; and we cannot, therefore, test the accuracy of Faraday's law until the value of the chemical equivalent of copper can be assigned with greater accuracy than appears at present to be practicable. We may, however, notice that the value 3.4086 is that which would be obtained with comparatively very small current densities, and occupies a place in the middle of a continuous series, and there seems to be no reason in the electrolytic behavior of the cells for accepting that value as indicating a limiting result. We may therefore fairly approach the question the other way, and, using the observations to calculate the chemical equivalent of copper by Faraday's law, consider the results which follow. If we assume, as we seem fairly entitled to do, that the differences of the weights for different current densities are due to the solution of the deposited copper, it follows (assuming Faraday's law) that we must get a nearer approximation to the true amount of copper equivalent to the amount of silver deposited the greater the current density. The value would be affected by the correction discussed above; but it has been already stated that it is unsafe to apply the correction, or, at any rate, to assign to the value that of k' assigned above. But the consideration of that correction serves us to this extent, viz., to show that for current densities above .02 its value must be very small indeed, reaching, as a matter of fact, with the value of $k' = .00002$, to less than one milligramme per gramme. But in determining by Faraday's law as accurately as possible the chemical equivalent of copper from that of silver, the correction cannot be disregarded without sufficient reasons. Some reasons for that course have been given, but in order to test further whether or not the correction should be applied I have plotted the observations on sectional paper, taking as ordinates the ratios of copper to silver, and as abscissæ the reciprocals of current densities. If the correction should be applied throughout, the grouping of the observations should show a straight line inclined to the axis of current densities. I have adopted this method of combining the observations belonging to different experiments for this purpose, in preference to the arithmetical one of taking means, because the latter is liable to be seriously affected by a set of observations, each one of which is far from the mean in the same direction, but which does not extend throughout the whole range. In the estimation by eye of a mean result of plotted observations allowance can be made for the effect such observations produce, whereas they may give a false appearance of general law to a set of arithmetical means.

TABLE V.

Current densities.	Ratios observed.	Ratios with the correction ($k' = .000012$)
.124	3.3968	3.3965
.104	3.4005	3.4001
.094	3.3984	3.3979
.072	3.3971	3.3965
.064	3.4004	3.3997
.062	3.3994	3.3987
.052	3.4035	3.4027
.051	3.3982	3.3974
.046	3.4009	3.4000
.036	3.3984	3.3972
.032	3.3990	3.3977
.031	3.3998	3.3984
.027	3.4014	3.3998
.026	3.4056	2.4040
.025	3.3982	3.3966
Mean	3.39983	3.39888
Mean error	.00175	.00151

The observations included in the table ii. when plotted do not give any indication of the divergence of the mean ordinates from a straight line parallel to the axis of reciprocals of current densities until the current density is less than .02, and the straight line passing through the "centre of gravity" of the group of observations for highest current densities, and inclined to the axis with the angle given by the value $k' = 000025$, would leave all the rest of the observations except three on one side of it; but a very

Digitized by Google

fair result is obtained if the value of k' be somewhat reduced, and the line be drawn at the corresponding less inclination through the point corresponding to the "centre of gravity" of observations about the current density .02. If we must take a straight line inclined to the axis as representing the results, the one which must be selected has an inclination to the axis of about one-half that given by $k' = .000025$, and even that leaves on one side of it nearly the whole group of observations whose current densities have reciprocals between 50 and 30. Further, the values of the ratios obtained from the observations for current densities above .02 are remarkably close, except in two instances; in one the ratio is very high, with a high current density, and differs widely from other observations at about the same current density; the other is very low, and belongs to an experiment which gives a series of very low values; this has been rejected because the wire which gave it was marked in the note-book as discolored, *i. e.* oxidized, at the time of weighing.

In order, therefore, to obtain the value of the chemical equivalent by this method, I have taken all the values obtained for current densities greater than .025 ampere per square centimeter. They are included in table v.

I have included in the same table the values obtained when the correction for the current density ($k' = .000012$) is introduced, in order that an opinion may be formed as to the magnitude of the difference produced. It will be seen that the amount of difference corresponds to an error in weighing of only 0.3 milligramme per gramme. I have given reasons for preferring the value as calculated without the introduction of this correction, and from the circumstance already pointed out, viz., that after the correction $k' = .000025$ is introduced, the "2 wire" values are minima, it would seem likely that the deposit obtained with the highest current density may be too great in consequence of the operation of some action which is not accounted for. To decide this point requires measurements to a degree of accuracy beyond that reached in the present observations, so that we may set down the ratio of the chemical equivalent of silver to that of copper, as obtained by this method, as being

3.39983,

with a mean error of $\pm$ .00175 in the observations.

THE ATOMIC WEIGHT OF COPPER.

It will be at once noticed that the value obtained for the ratio of the equivalent differs by only 17 parts in 300000 from the number 3.4000, and there is some indication that the observed value is too small; we may therefore accept the observations as showing the ratio to approach very nearly indeed to 3.4000. This gives for the ratio of the atomic weight of silver to that of copper the ratio of the whole numbers 17 : 10. If we take the atomic weight of silver as 107.66, the atomic weight of copper will be 63.333. This result gives some striking relations; it gives, in fact, for the atomic weight of silver the number $\frac{19 \times 17}{3}$, and for that of copper $\frac{19 \times 10}{3}$, and therefore gives both as one-third of whole numbers. The atomic weight of silver is one of the most accurately determined of all, and the number here assigned to copper is within the limits of error allowed by L. Meyer; so that these remarkable relations may perhaps offer some reason for considering the value of the atomic weight of copper as deduced from Faraday's law as being worthy of consideration.

A number of speculations are suggested by the relations between the numbers thus arrived at; but it is not necessary to discuss them here.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Sleet Storms of the Season.—No Prospect of Subways Just Yet.—The Richmond Hotel Fire.—The Sad Death of Robert S. Boyd.—Electric Train Lighting.—Telegraph Operators to Enter Into Competitive Telegraphy.—Arc Lights as a Protection Against Burglars.—The Orange Electric Railway.

THE various companies owning overhead wires may congratulate themselves that they have escaped serious damage from sleet and snow storms in New York city during the past winter. On two occasions just as the ice had approached that point in weight which brings down wires, fixtures and poles, in the relative order of their weakness, the weather has changed and a considerable loss avoided, which will not come amiss in placing the wires underground, provided the various subterranean litigants will permit any work to be done during the present season.

Two important tenants, whose rentals would be appreciated—the Western Union and Baltimore and Ohio Telegraph companies—are stringing aerial cables to a considerable extent.

The burning of the new Richmond Hotel, at Buffalo, on the morning of March 18th, was an event which attracted the attention of the public to the dangers of overhead wires, by reason of the difficulty experienced in raising ladders to rescue the guests before they were burned to death. The thorough manner in which the inmates were aroused by the guest call and fire alarm, should not be lost sight of. Had this important feature of a first-class hotel been omitted, doubtless the number of victims, 15 in all, would have been largely increased.

Among those who lost their lives was Mr. Robert S. Boyd, a special agent of the American Bell Telephone Company, who went from Syracuse to Buffalo the previous day, and who was assigned to room 175, according to the hotel register, taken from the ruins 7 days later. Mr. Boyd had made a large circle of friends among the telephone fraternity, and the sad confirmation of the first rumor that he was among the dead, has brought to them a realizing sense of the shocking character of such accidents, which appear to have been more prevalent than usual during the past few months.

The various railway disasters in which the demolished cars have taken fire from overturned stoves or lamps, have directed attention to the heating of coaches by steam and lighting them by electricity. So far as the lighting is concerned, electricity has been used to a limited extent for that purpose on the Pennsylvania railroad for perhaps two years. Special attention has been, of course, directed to the economy of the system as compared with oil or gas. It is to be hoped that at some period, in the dim future, due attention will be given to the question of safety of life as well as economical operating expenses.

It was once the supposition that a telegraph operator if he continued to practice his profession, must remain an employe for the period of his active life. the ownership of a revenue earning telegraph line being out of his reach. This is all to be changed, and the modern telegrapher, if he can secure a good partner at some distant commercial centre, may, like the cobbler or the barber, aspire to the proprietorship of an establishment adorned with his own shingle. All this is to be brought about by the leased line system operated by the Delany Multiplex Telegraph. During the next three months a 20 wire line will be constructed between New York and Boston, each of these wires being subdivided into, say, a dozen circuits. These circuit privileges will be leased at a rental within the reach of the poor laboring man, who, if he is popular in any of the great mercantile centres, such as the dry goods, leather, oil or stock markets, may secure a select class of customers who wish to encourage competition. In this event we may look for a most curious revolution in existing tariff systems, in which rival establishments will give 25 per cent. off the list, and 5 per cent. more for spot cash. When this has brought the business down to hardpan, syndicates and pools will follow, and embrye Jay Goulds will be developed fresh from the ranks. All of this depends merely upon the practical success of Mr. Delany's system, and this is believed to be assured by those who are familiar with it and are competent judges of its possibilities.

Mrs. Hicks-Lord, whose residence was recently robbed of valuable silverware, has petitioned the city authorities for permission to maintain an arc lamp in front of her premises, at her own expense, as a protection against marauders in the future. In a suburban city several residents refused to subscribe toward the support of electric street lighting, on the plea that they were not run after 1 o'clock A. M., although the old naphtha lamps were allowed to burn out at that hour. Speaking of recent burglaries, one of the non-subscribing citizens said it was a shame that the electric lights were not run all night. When reminded that they were kept up as long as the old lamps were, he remarked, "I know that, but it *seems* so much darker now than it did before."

The opening of the experimental section of the electrical street railway in Orange, has been delayed by inclement weather, but is expected to be in operation early in April. No arrangements will be made to introduce horses until after the authorities have made up their mind, upon the subject of permitting the introduction of electricity permanently for such service.

NEW YORK. March 25, 1887.

PHILADELPHIA.

Action of City Councils on Electrical Franchises.—Report of D. R. Walker, Chief of City Electrical Departments.—More Electric Light for Philadelphia Streets.—Proposed Rules for Electric Light Installations.

AT a special session of select council recently, there was a sharp discussion over the report of the electrical committee on the ordinance granting permission to the Penn Electric Light Company to lease its conduits for electric purposes and for pneumatic tubes. A member moved to postpone consideration of the subject, saying: "We have just granted them all the privileges they asked and they have done nothing to fulfill their contracts. Now they come before us again and ask for further

Digitized by Google

privileges, which may be worth thousand of dollars." Another member, in defense of the ordinance, said: "This is all nonsense. This company comes to us as all the others have come. The Keystone company has been held back, not by councils, but by the board of highway supervisors, because there are eleven suits for infringement of patents pending against it. The company has never reached councils. The Penn company has partially established its system, and desires to extend it further. Now, if they have more room than they want, and wish to rent it, what business of ours is it? Why should they not rent their conduits? Must there be a dozen others laid?"

Mr. Monroe characterized the ordinance as a stock-jobbing operation, and urged that it be laid over for the new councils to consider.

The vote on the ordinance as finally taken was, yeas, 20; nays, 6.

A communication was read from the Keystone Electric Light and Power Company protesting against the passage of the Penn ordinance, as it was claimed its passage would give the latter a monopoly over the streets of the city.

Mr. Abrams claimed that the Keystone company's complaint was founded upon its inability to obtain the privileges that had been conferred upon the Penn company. He stated that the Keystone represented the Standard Oil Company, which had acquired control of all the existing electric light companies in the city.

David R. Walker, chief of the electrical department, has submitted his third annual report to Mayor Smith. After referring to the removal of the fire alarm department to its handsome quarters in the City Hall, it gives a minute account of the beginning of a permanent system of underground works for the municipal electrical service.

It also speaks of the lighting of the highways by electric lights, supplied with their currents by the underground wires, and of the extension and improvement of the municipal service, under the control of the electrical department.

It describes the result of the trial of underground electric light service, for which $2,500 was appropriated, and after giving the exact locality where the trial was made, it gives a detailed account of the entire trial, and shows conclusively its entire success.

Attention is also called to the fact that none of the telegraph, telephone, or electric light companies have made any attempts to place their wires underground or to remove their poles from the streets. They are, however, required to make full returns, and a strict account of this is kept by the chief, and should a change of legislation permit, license charges will be collected.

The report continues:

The total returns made for poles, wires, conduits, attachments to city poles and mileage of wire amount to $23,586.50, of which amount $7,149.50 has been paid into the city treasury, leaving unpaid $16,357, a portion of which is in the hands of the city solicitor for collection. According to the returns made to this department there were, on December 31, 1886, on the highways of this city 5,053 poles, exclusive of those along railroad tracks and city poles, being an increase of 231 poles over 1885. Four thousand four hundred and ninety miles of telegraph and telephone wire, being an increase of 122 miles; 204 miles of electric light wire, being an increase of 47 miles, and 595 miles of city wire, being an increase of 57 miles, making a total of city and all other wires 5,289 miles, being an increase of 226 miles over the previous year. The increase of poles was mainly due to the extension of the electric light service for lighting the public highway. On December 31, 1886, there had been laid underground in the city, 472.6 miles of telegraph, telephone and elec tric light wire, of which the city owns 21.6 miles.

The chief recommends that as the lighting of the thoroughfares has reached its present state the city should establish its own plants for electric lighting. As the municipality owns the gas and waterworks it could consequently furnish the power from them; there would be little additional expense for that agent. The outlay for conductors, lamps, dynamos and other machinery would be the greatest expense, and the saving in the amount now paid to private companies would off-set in a great degree.

The report goes on to say that at the close of the last year there were 198 electric lights, and at the close of 1886 there were 354, an increase of 156 over the previous year, maintained by the city for lighting the public highways, at an average cost of 53¾ cents per night. There were extinguished during the year 312 gas and gasoline lamps, of which 285 were by the Philadelphia Gas Works, 26 by the Northern Liberties Gas Works, and one gasoline lamp, making a total of 737 lamps extinguished where the electric light has been introduced.

The chief recommends that an inspector of electric lights be appointed, and refers to the Temple theatre fire as an instance of the necessity of such an appointment.

The report concludes with the following recommendations for incandescent installation:

"First—Lamps should not be placed in close proximity to inflammable material. The breaking of a lamp will scarcely ignite inflammable solids, but will ignite inflammable and explosive gases or mixtures if present.

"Second—Avoid trusting wire joints without soldering. Any accidental cause may induce the formation of an arc, which might be avoided if the joint were prevented from shaking loose or opening by soldering.

"Third—Use only uninflammable waterproof insulation for the entire system.

"In the case of paraffine and cotton insulation the overheating of the wire by too heavy a current will melt the insulation for its whole length, and on ignition it acts like a taper and flame conductor. If the insulating wire is not waterproof there is the danger of a circuit from rain or water or the condensation of steam.

"Fourth—The use of safety plugs of standard proportion to act as cut-offs if currents become of too great intensity.

"Fifth—Installations to be made entirely by companies, which should assume responsibility for their employés.

"Sixth—Issuing of a permit to use a current only after the department has inspected the covering.

"These are well-known rules to experts in electrical matters, but not as familar to the general public. The very high potential of the series arc system demands that these wires should be kept separate from all others and requires precautions in insulation. The well-known fact of the danger attendant upon the handling of circuits has acted to prevent loss of life on the part of the general public, but accidents to the employés of the companies do occasionally happen because of neglect incidental to familiarity."

The electrical department is busied making arrangements for the 162 new electric lights to be placed in position in this city. It is expected that they will be in operation by April 1st, or as soon as the lamps and fixtures can be erected and the wires run. From 12 to 15 lights will illuminate Broad street from Fairmount avenue to Columbia avenue.

The electrical committee of councils have agreed to report an ordinance favorably to councils, giving the American Long Distance Telegraph and Telephone Company the right to lay conduits all over the city.

PHILADELPHIA, March 17, 1887.

BOSTON.

Proposed Legislation to Regulate Telephone Charges.—Quarterly Report of the New England Telephone Co.—The American Bell Telephone Co.'s Output of Telephones.—The Government Telephone Suit.—U. S. Signal Service Line on Martha's Vineyard.—An Underground System.—Electric Lighting on the Boston & Albany R. R.—Electric Lighting at Newton.—Burning of the Lighting Station at East Boston.—Electric Railways.—Boston Fire Alarm.

ON Wednesday, February 23, the Assembly committee on Mercantile Affairs took up that portion of the proposed legislation relative to the limiting of telephone rates. Mr. George H. Stevens, of Lowell, appeared for Mr. Qua, who was unable to be present. Hon. R. M. Morse, Jr., and Hon. George A. Bruce represented the interests of the American Bell Telephone Co., and Mr. F. H. Williams, the New England Telephone Co. Mr. Stevens submitted the following bill, drawn by Mr. Qua:

Section 1. No individual, company, or corporation now or hereafter owning, controlling or operating telephone lines in this state shall charge, collect or receive as rental, royalty or commission, for the use of telephones with their respective appliances, a sum in excess of that hereafter named, as follows: In telephone exchanges serving a territory with a population less than 10,000 persons, $3 per month, where one set or pair of telephones is rented by one individual, company or corporation, provided such telephones are located or operated at any point within one mile of the central office of such exchange, and for each additional mile or fraction thereof, not more than an additional sum of 50 cents per month shall be charged as aforesaid for the use of such telephone. In telephone exchanges serving a territory with a population of over 10,000 persons and less than 100,000 persons, an additional charge of $1 for each subscriber per month may be charged for the use of each set or pair of telephones. In telephone exchanges serving a territory with a population of 100,000 persons or more, the charge for each set or pair of telephones shall not exceed the following rates: Within one-half mile of the central office, for special wires limited to one subscriber, for business purposes, $5 per month; for residences, $4 per month. For wires limited to two parties, for business purposes, $4.33 per month; for residences, $3.33 per month. For wires having four or more subscribers, for business purposes, $3.50 per month; and for residences, $2.50 per month. Fifty cents per month additional to above rates in the territory last described may be charged for each additional half-mile of distance from the central office of such exchanges.

Sec. 2. When any two cities and towns are connected by wires operated or owned by any individual company or corporation, the price for the use of any telephone, for the purpose of conversation between any such cities and towns, shall not exceed 15 cents for the first five minutes, and for each additional five minutes no sum exceeding five cents shall be charged, collected or received.

Sec. 3. Any owner, operator, agent, or other person, who shall charge, collect or receive for the use of any telephone, any sums in excess of the rates fixed by this act, shall be deemed guilty of a public offense, and on conviction, shall be fined in any sum not exceeding $25.

Sec. 4. This act shall take effect July 1, 1887.

Testimony was given to show that the rates charged by the American Bell are excessive; that the service is insufficient, and that the business is done elsewhere with profit at rates lower than exist in Massachusetts. The witnesses were Dr. S. P. Hubbard of

Digitized by Google

Taunton, Dr. George Morse, of Gloucester, and Edward A. Birge, of Lynn. The hearing will be continued.

New England Telephone Co. The statement of earnings and expenses for the last quarter of 1886 issues this afternoon, and in comparison with the corresponding quarter of 1885, substantial increases are shown in gross and net receipts, but heavy charges to construction result in a decreased surplus. For the year a slight falling off is shown in gross, but decreased expenses result in increased net earnings, while the surplus over construction was nearly 20 per cent. larger for 1886 than for 1885. Full details are shown in the following tabulation :

Quarter ended December 31—	1886.	1885.	Increase.
Gross earnings	$346,239	$321,100	$15,139
Operating expense	171,226	167,079	4,147
Net earnings	$65,013	$54,021	$10,992
Construction	34,972	1,458	33,514
Surplus	$30,041	$52,563	*$22,522
Year—	1886.	1885.	Increase.
Gross earnings	$917,611	$920,581	*$2,970
Operating expense	659,695	668,092	*8,397
Net earnings	$257,916	$252,489	$5,427
Construction	37,819	68,461	*30,642
Surplus	$220,097	$184,028	$36,069

*Decrease.

The output of telephones by the American Bell Co. for the month ended February 20, and the first two months of the fiscal year, is herewith tabulated :

February	1887.	1886.	Increase.
Gross output	3,405	3,223	182
Returned	1,918	1,408	510
Net output	1,487	1,815	*328
Dec. 21 to Feb. 20—	1886-7.	1885-6.	Increase.
Gross output	7,379	6,003	1,376
Returned	3,874	2,956	918
Net output	3,505	3,047	458

*Decrease.

Comparison with previous months—

	Feb.	Jan.	Dec.	Nov.	Oct.	Sept.
Gross	3,405	3,974	3,946	3,340	3,259	3,800
Returned	1,918	1,956	1 686	1,825	1,745	1,258
Net	1,487	2,018	2,260	1,515	1,514	2,542

In the case of the United States *vs.* American Bell Telephone Co., a motion has been filed by defendant for leave to plead certain facts in addition to filing a demurrer to the bill. It alleges that, inasmuch as the bill in this case refers to litigation and controversy formerly had with reference to the validity and scope of the patents which are the subject-matter of the bill, but does not state the result of such litigation, or the decisions made therein, or the fact that questions of fact and of law sought to be raised by the bill in this case have been argued before the Supreme Court in suits for infringement of these two patents, and are now held under advisement—the proper course for defendant is to plead these facts in order to bring them before the court. For that reason it asks leave of the court to plead any and all determinations, had, relating to, or affecting the validity and scope of said patents and to the facts upon which their validity or scope depends, in addition to filing a demurrer, and represents that the questions which it desires to raise by such plea are closely akin to those which would be raised by demurrer, and that much time, expense and labor will be saved by presenting and arguing them at the same time. It further desires to present in this way copies of certain written communications from the commissioner of patents to Elisha Gray, dated February 19 and 26, 1876, which are referred to in the bill, but copies of which are not annexed thereto. Defendant says further that the litigation heretofore had under the said patents has resulted in records filling twenty thousand printed pages, including more than seven hundred depositions, which have required many years to take and which have cost each side not less than $300,000 ; that such records are now before the United States Supreme Court on appeal, and have been the subject of 12 days of argument there, and are now held under advisement. The defendant further says that it would be indecorous and contrary to the practice and usages of the Court of Equity to re-try any questions pending before that court until it shall have pronounced its opinion and judgment, or to require such expensive litigation to be repeated in this case until the questions of the power and authority of this court to entertain this bill, and the propriety of its so doing as a court of equity, have been fully determined, upon the facts stated in the bill, and upon a consideration of the results of the suits and litigation referred to in the bill, but not fully stated.

On Monday, March 14th, a hearing was had in the U. S. Circuit Court, upon the above. Messrs. Storrow and Smith appearing for the American Bell Co., and Messrs. Goode and Jeff. Chandler, for the government. The court took the case under advisement.

The government has set up a telephone line connecting the signal station at Vineyard Haven with Gay Head, and when a pole has been set up cautionary signals can be displayed from a point near the lighthouse. The line can be used by masters of ships wrecked in that neighborhood for summoning assistance from Vineyard Haven.

Representatives of several telephone, telegraph and electric light companies went out to Brighton on the afternoon of the 2d inst. to inspect a new arrangement for carrying underground wires—a conduit recently patented by the American Conduit Company. These gentlemen, recognizing the fact that eventually all wires must go underground, have after three months of experimenting succeeded in perfecting a machine for the manufacture of what they consider an imperishable conduit. They claim that it is practically indestructible, and that it can be manufactured and put underground at a cost less than is required to keep wires and poles above ground in repair for a year. The conduits are manufactured from cement and sand, and after being shaped are treated to a bath of hot asphaltum, which makes them impervious to water and perfect insulators as well. If the system of heating business establishments and houses by steam from a central station through underground tunnels should ever be adopted, these conduits could be used for running the pipes. This is understood to be the "Richardson system."

Within the last few weeks many passengers on the Boston and Albany Railroad have noticed one car that was lighted by incandescent electric lamps. The power for the lamps is derived from a storage battery beneath the car. The apparatus was placed on the car by the Julien Electric Company of New York, which holds letters patent in this country for the Julien storage battery. The car equipped on the Boston and Albany was the first trial of a system on a railroad in this country, and its surprising success has led that road to order other cars equipped as fast as possible, and has created much interest in the subject on the part of other prominent railroad companies.

The car carries twenty-four sixteen-candle power incandescent lamps, and the power is furnished by a Julien storage battery of 60 cells, which will keep all the lights burning for 10 hours. Each cell consists of 19 plates, weighing in all twenty-seven pounds, and measures 6½ by 5¾ inches, and is eight inches high. These cells are combined in boxes for convenience in carrying and in charging, and the whole battery of 60 cells weighs about one ton. With the ordinary lamps removed, the car presents a novel and handsome appearance, and when the current is turned on it is lighted with a clear and steady light, with which oil cannot compete, Passengers find the light agreeable to read by, the train hands have no trouble with smoky lamps, and best of all, the danger from fire in case of accident is entirely removed. This car has been running now for thirty days, and thus far but one lamp has been broken, and at no time has any trouble been experienced with the light.

At a meeting of the board of aldermen, of Newton, on the 21st ult., the electric light question came up. The committee on street lights reported in favor of making a contract with the Newton Electric Light and Power Company to furnish the city from March 1 to June 1, with 30 arc lights, of not less than 1200 c. p., and 84 arc lights of the same power from June 1 next to June 1, 1888. Said lights to burn every night from sunset to sunrise, and for the sum of 50 cents per light per night. An order covering the above was presented, discussed and finally referred back to the committee, with instructions to ascertain the expense of lighting the principal squares and streets according to the "moon schedule," or on such nights in the year as the moon does not shine.

At East Boston, at about 6.55 o'clock, on the morning of the 6th inst., a fire occurred which destroyed the two-story wooden building, sixty feet long and twenty-five feet deep, on Condor street, occupied by the Citizens' Electric Light Company. The building was an old one, valued at about $1,200. In it were several dynamos, valued at about $8,000 or $10,000, which were considerably damaged. The cause of the fire is unknown.

The visit of the Boston aldermen to Scranton, Pa., is significant, if for no other reason, from the fact that it so closely follows a call of inspection recently made to the same locality by several of the gentlemen composing the West End syndicate to judge of the practical working of the electrical street railway now in operation there. According to one of the visitors, Mr. Henry D. Hyde, they all came away satisfied that electricity as a motive power for street railways has come, and while many details of application and convenience will yet be added to it, the success of the thing seems to be assured. The car was geared for running five miles an hour up the heavy grades, and on the level stretches fifteen miles an hour. Both rates of speed were easily made, and the car ran easily, steadily, and was in full control of the driver, if he may so be called. The motor is placed upon the front platform, which is enclosed very much like a pilot house, where also is a hand brake, by which the speed of the car is controlled and checked. The whole handling of the car is very simple and effective, and over all suburban routes it would seem as though it can go into immediate operation. In the more thickly settled portions of a city like Boston, there are some objections to overhead wires, which no doubt will at an early day be overcome. The electricity is conducted by a wire suspended from cross wires across the street, and there seems to

Digitized by Google

be no more objection to this form of using electricity than comes from telegraph, telephone and electric lighting. Mr. Hyde continuing, said, "None of us, with the exception of Mr. Frank L. Pope, had any special knowledge of electricity or its application, and yet the whole arrangement seemed to all of us very simple and effective, and I shall look for as rapid a development of electricity as a motive power in the propelling of street cars as we have seen in the improvement of the electric light since it first came, and it seems at once feasible and practicable, as I have said, for suburban purposes. We have made arrangements for taking an unoccupied street upon the Back Bay and at once placing a car in operation, with the leave of the city, upon which we propose to try the different forms of applying electricity which are now being offered."

For some months the Boston fire commissioners have been experimenting with the system of turning fire alarms into the permanent engine houses only in the districts where they exist, discontinuing the striking of the tower bells wherever possible, as in other large cities. The plan has worked so satisfactorily, that they have to-day extended the area over which the general public will be left uninformed of the existence of fires, except by a sight of the passage of an apparatus through the streets. All bells north of Dover street are now silent when an alarm is given except the six-thousand-pound bell on Faneuil Hall, which will be kept in the system until further notice. The business part of the city, with the exception of the vicinity of Faneuil Hall, will be spared the infliction of the sounding bells and the consequent crowds they draw to fires, however slight they may be. The outlying districts, however, will be informed of fires in their locality, whether by day or by night. The police stations, the insurance and newspaper offices are connected with the system by direct wires, so that the down-town public, while having no instantaneous information, are not deprived of facts when they have come to pass.

CHICAGO.

Failure to Repeal the Indiana Telephone Legislation.—Exhibition of a Large Van Depoele Dynamo.—City Electric Lighting.

IT was expected that Indiana would go back on her record. It was believed that the Solons of the state, after two years of growl and grab in the telephone business, would, as far as lay in their power, undo the mischief they had unwittingly accomplished through knowing so much about the business; but Indiana can be depended upon as well as one can rely on the finding of a petit jury. One thing is always on top down there—politics. When the party horn blows, the rank and file fly to the standard, dress to the right, and stand at attention. Then, instanter, the old-time fight commences; business falls to the rear; important measures of public weal are as chaff in the breeze; the banner of the party is waving, the long roll has sounded, and "whoop, huzza, and away we go," and may the proprietor of the old Calvinistic bake-oven take the hindmost.

The repeal bill which had passed the house had proceeded as far as the second reading in the senate, and would have certainly become a law had it had one more chance for its life. It went by the board—was laid over indefinitely, because so much time had been wasted in the political squabble, and because a clause in the constitution limits the duration of the session. It is well that there is a limit to a legislative session in Indiana. Were it otherwise, there is no knowing what result might be reached by the wise men of the Hoosier state. There may be an extra session. The governor, in the event of calling together the Solons, must state specifically what questions are to be considered. These, and these only, may come before the legislature in an extra session. There were so many other questions of importance left in an unfinished condition that it is highly improbable so little a thing as a telephone rate should be among the matters for consideration; and, beside, there is little prospect of an extra session. Should we all live, we may possibly hear of the repeal bill two years from now, but—it's in Indiana. Let us hope that justice may yet perch above the capitol of Indiana, and—stop, right there! Not one share, sir—not one share! Let us change the subject.

Several gentlemen, including members of the press, were invited on the 15th to witness the labors of Van Depoele's monster generator, built for the Montgomery, Ala., street railroad system. This road, in all its ramifications, covers a linear track of about twelve miles. The machine—of 250 h. p.—has been very properly christened the GIANT. It stands four and one-half feet high in its stockings—that is, on its base—is nine feet in length from heel to heel of magnets, and has an armature shaft seven feet long. The weight of the little gem is about six tons! The general form of the giant is that of the typical Van Depoele dynamo, and it is excited by a similar small machine. The GIANT running at 380 revolutions, was generating 500 volts pressure. The fields, which are energized by an exciter dynamo, were receiving about three amperes of current, and the dynamo was running twelve single car motors, absorbing about three amperes each—without load—in multiple arc. The arrangement of the brushes in these motors is such that reversals are made by changing contacts, there being two pairs of brushes. When the quadrant is on the centre neither brushes touch; when moved to the right one pair, and when moved to the left the other pair, are put in contact, giving it either a forward or backward motion, at will.

The little motors are less than three feet high, and very compact. The driver has complete control of the machine, a horizontal crank, with a sweep of a little over half a circle, doing the work. Two-thirds of the way round is a spring stop, which is the point of greatest efficiency of one form, while, beyond this, the course of the current is changed by shunts running into the field magnets, giving a greater but different form of work. While speed is required, or desirable, at times, at others—as in climbing a grade, or when hauling extra heavy loads—less speed and more pull may be necessary.

The time draws near when our city council either will or will not inaugurate a proposed scheme, which is to be the commencement of the end, in the matter of bridging, for the good people of Chicago, on their way morning, noon and night, from one side of the river to the other.

Professor J. P. Barrett, to whom the city is almost solely indebted for the underground movement (the professor was the original and only "ground hog" for a long time), is doing his level best to get the council to appropriate $75,000 for a city plant of arc lights along the shores of the river, from Chicago avenue to 22d street, and from the junction of the rivers to Rush street. This was referred to in this column in the January number of THE ELECTRICIAN AND ELECTRICAL ENGINEER, but at that time the matter was vague and uncertain. The question of bridging, as summer approaches, is becoming an argument of high potency, and the fact that, in a few weeks, at the most, the howl of the tugs and the fearfully-long strings of waiting street cars and vehicles will make life a burden to the business man, or the belated traveler, cannot be overlooked or forgotten. Something must be done; and this move, if the council will but look at it in the proper light, and give the professor his wished-for appropriation, will do wonders, and save thousands of hours every day to the community, by lighting the waterways so perfectly at night that the passing vessels may do their coming and going without hindrance after business hours, and leave to the good people for whom the bridges were made an opportunity to use them in daylight.

But it must be done before the first of April, or wait for another year. Let us hope.

CHICAGO, March 15, 1887.

SAN FRANCISCO.

The Postal Telegraph Company's Pacific Lines.—A New Pacific Railway.—Western Union Notes.—An Electric Street Railway for San Francisco.—Success of the Electric Railway at Los Angeles.—A Storage Battery Company.—New Quarters of the Pacific Bell Telephone Company.—Underground Wires.—Service on "Postal" Lines from San Francisco to Portland.—"Col." Tichenor and his Mud Battery.

THE Postal Telegraph lines are not yet open for public business, nor can the management say definitely when they will be. They have learned that 1,200 miles of telegraph line cannot be built and completed satisfactorily, in three months. Mr. Rosener thinks the writer did them an injustice in his last letter, by not making allowance for the innumerable difficulties they have had to surmount. No one appreciates these more than the writer, hence he raised a warning voice that it would be unwise to open as early as even the first of March, with only a northern outlet to depend upon. Mr. Rosener has seen the wisdom of waiting. The criticism upon the manner in which the line between here and Port Costa was built, was based upon personal observation. It is now learned that the whims of farmers have compelled the "Postal" to remove poles and place them in some of the most outlandish places before granting right of way through their grounds. From Redding to Yreka, over the Shasta mountains, is the worst piece of territory in America on which to build lines; and it is about as bad through the timber country north from Tacoma to New Westminister, B. C. Wires in this section will be at the mercy of falling trees for at least six weeks yet; but, the management give assurance that when they do open they mean business and are in the field to stay. It is rumored too, that at an early day they contemplate building a southern outlet. This is as it should be, and it is safe to say that, profiting by their northern experience, the southern line will be built in a manner to command admiration and disarm criticism.

Mr. James Gamble has been elected president of the United States Central Railway Company. This company proposes to build a railway from Alameda or Berkeley through Centra Costa county, San Joaquin valley, into Inyo county, southern Nevada, southern Utah and Colorado, there to form a connection with eastern roads. It will be a short route and will pass through the

Digitized by Google

finest territory on the Pacific slope. Mr. Gamble may leave for New York in a few days to confer with some of the millionaire railway magnates. He declines to give an opinion on the future of the "Postal," as he thinks it is too early, and he wants to see what other connections they will secure.

The Western Union have now a No. 11 copper wire between here and Chicago, except across the bay, where there is no cable competent to meet it. In May a new one will be laid, which will be able to bear a large battery. We are told it will be worked "Wheatstone." We are told also it will be worked "quad." What will really be worked, time alone can tell. Experience with the Wheatstone between Chicago and New York ought to indicate that it will never do for overland business unless competent operators are employed for punchers and transcribers. If the Western Union uses Wheatstone the innumerable "bulls" consequent, will drive many a disgusted customer over to the "Postal."

The manner in which the Western Union men have been worked for the last two months in this city, is simply shameful. The hours often include 3, 5 and 7 hours extra service a night without a cent compensation. It is not because wires are in trouble, it is the extraordinary amount of business and reports transmitted; and yet in the face of this great rush insufficient force is kept on to meet the volume of business. Ambitious chief operators, who desire to make a name for themselves at the expense of their fellow-men, merit the just condemnation of all, and sooner or later the boomerang will return and smite the hands that flung it. It is a poor policy.

A party of gentlemen met at the residence of Adolph Sutro, in this city, a few weeks ago, including Messrs. J. W. Mackay, S. Rosener, M. C. Laven, George Roe, N. S. Keith and Mr. Speed, to discuss the practicability of an electric railroad along Harrison street, south of Bernal Heights and the Patrero. The system represented by Mr. Speed was finally adopted, as it is running with a great deal of success in Denver, Colorado; and it was determined to experiment on it for a distance of about four or five blocks on Fillmore street hill, the Brush Electric Light Company supplying the power, each car having a separate motor. If this is successful, it is safe to say, a line will soon be established from the ferries to Point Labos and Sutro Heights (old Cliff House). Such a line would afford the greatest interest to visitors, as it would command a view of the Golden Gate, the Presidio, Lime and Fort points, and the Pacific ocean.

The electric railway in Los Angeles is running very satisfactorily for a distance of about three miles, and it is safe to predict, that with a little time and consequent improvements it will supersede the cable system.

The Pacific Accumulator Company has been formed with George S. Ladd as president, and Messrs. Moriarty and Armstrong, of New York, as directors. It will occupy the Fair building on Pine street with the Pacific Bell Telephone Company, which has recently moved thither. One cannot easily do justice to the manner in which the Pacific Bell Telephone company has fitted up its offices and operating rooms. It has the entire five stories. The upper one contains Mr. Sabin's office and operating room. Here is the Western Electric multiple switch ($25,000) with a capacity of 4,000 circuits and operating 2,000. It is a wonderful piece of mechanism. At one end of the room is a section exclusively for the Sunset Telephone Company, which means country connections with Sacramento and intermediate towns on one side and Santa Cruz and intermediates on the other. On the next floor below, is Mr. Ladd's office, fitted up in a gorgeous manner. Here is a magnificent book case presented to Mr. Ladd years ago by the employés of the Western Union, when he retired from that company. The case was too large for a private dwelling, and Mr. Ladd has placed it in his new quarters. The lower floor is for the public and supply rooms, as well as a cloak and lunch room for the women employed as operators. This is in charge of a woman who cooks for them and cares for their clothing. It is worthy of mention that the company furnishes the lunch and an occasional cup of tea *free*.

The Telephone company has purchased cables and all the necessary material for laying underground conduits, and is urging the present board of supervisors to grant a franchise. It is to be hoped that it will be obtained. The mayor and chief engineer of the fire department are favorable to granting the franchise. Six supervisors are all that is needed.

Mr. Atchison, superintendent of construction of the "Postal," will leave for the east in a few days. Had he been here earlier, a few errors would have been obviated.

Many a telegraph office is neat, some are handsome, but such a *bijou* as the "Postal" have here is a rarity, if not unique. It is simply perfect. It should be noted that the duplex circuit to Portland, 800 miles, works without a repeater, the signals being as *clear* as on a city wire. If the remainder of the wire east works equally well, there will be no need to introduce Wheatstone. Good men on such wires can double discount any Wheatstone ever worked—day in and day out.

"Colonel" Anson C. Tichenor has come to the surface again, this time as the inventor of a famous scheme for making electricity out of mud and water. The first utilization of this marvelous force has been made at the Baldwin theatre. In the basement under the stage a friend of Tichenor's was found keeping guard over the mud machine, a great double battery of no less than 126 cells. At the bottom of each of these cells there had been plumped, so the guardian said, about a pound of the marvelous mud; water was poured in, and then, when the light was needed, the usual time-honored sheets of zinc and carbon were let down into the water, and hey! presto! the extraordinary electricity was generated. Under ordinary circumstances such a battery would produce a 2,000 candle-power light. What it did produce was a very bright spark of about 50 candle-power, whenever Mephisto brought his sword into contact with that of Valentine in the play on the stage above. The so-called mud is a soft clay slate found, so Tichenor's friend said, at Alameda and Aptos. It either contains a small proportion of chromic acid, say 2 per cent. or the acid is mixed with the clay after being dug up. When the water is poured on it the result is a weakly acidulated water, and this acting on the immense surface of exposed zinc in the 126 cells produces an electric spark.

SAN FRANCISCO, March 4, 1887.

LITERATURE.

PERIODICALS.

Industries; a Journal of Engineering, Electricity, and Chemistry for the Mechanical and Manufacturing Trades: London and Manchester (England),

A weekly, started in June last, has now reached its thirty-sixth number. It covers a broad field, treating a wide range of topics with much ability and judgment. Electricity receives a fair share of attention; the editors evincing a judicious discrimination in selecting for description and discussion the features of electrical science and practice most pertinent to the problems of the time. The mechanical execution of the journal leaves little to be desired; paper, printing and illustrations being of unusual excellence. The engraving of the elaborate triple expansion engines of the steamship "Ormuz," in the number for January 28th, is remarkable for its effectiveness.

Land & Rail, Birmingham, Ala., a monthly journal, of which the initial number, dated January, 1887, reached us some weeks ago, frankly announces itself "as the champion of the Real Estate and Railway Interests of the south." The industrial growth of the south in the last few years, particularly in Alabama and Georgia, has been so striking a feature in the life of the country, as to make any championship seem almost superfluous. The services of champions are usually in behalf of the weak, down-trodden or unfortunate—none of which terms can apply to the section of the South around Birmingham. Nevertheless, it is gratifying to see southern interest in real estate and railroad growth exemplified in the pages of a journal such as *Land & Rail*.

CATALOGUES AND PAMPHLETS RECEIVED.

From far off Santa Barbara, comes a little pamphlet, issued by the Board of Trade of that city, setting forth the beauty and salubrity of the location as well as the enterprise of its people. An electric light system is among the recent public improvements. The description of Santa Barbara with its soft climate, lovely surroundings, its roses and greenery, with the Pacific rolling at its doors, is very enticing to the busy worker of an eastern city.

The Woodhouse & Rawson Electrical Supply Co., of Great Britain, Limited, have sent us their complete catalogue, which is published by them at the price of one shilling. We do not remember to have seen a more complete catalogue of electrical goods. It not only gives the prices and full particulars of all the electrical supplies that are connected with Messrs. Woodhouse & Rawson's name, but we also notice the prices and details of goods of many other well-known manufacturers.

The price list gives particulars of electric lighting outfit, both arc and incandescent, including power, such as steam and gas engines, turbines, &c., electric bells, signals, telephones, and nearly every application of electricity—except telegraph instruments—are represented. The catalogue is well and profusely illustrated. This catalogue indicates that English firms mean to keep in the front as manufacturers and traders in electrical appliances.

Dr. A. M. Rosenbrugh sends us a pamphlet containing a reprint from the *Canadian Journal*, of his papers read before the Canadian Institute on Telegraphing to and from Railway Trains, and on Duplex Telephony.

ELECTRICAL NEWS AND NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

FOURTH SPECIAL MEETING.

Continuing the agreeable practice of an occasional meeting through the winter, preceded by a dinner, thirty members and friends of the Institute met at Cable's restaurant, March 15th, Mr. Frank L. Pope, President, in the chair.

The proceedings were as follows:

The President—Gentlemen of the Institute: It affords me great pleasure to be able to meet with you once more. I had begun to

Digitized by Google

think that I should not see you again during the season. I am glad to see so large an attendance here.

The subject announced for discussion this evening is the distribution of electricity by secondary generators. As you all know, the matter of the distribution of electricity for lighting, by induction apparatus, variously called secondary generators, transformers, converters, etc., is attracting a great deal of attention at the present time, although it is not a particularly new thing; in fact it has been in operation in one form or another constantly since the early part of 1883; it is, however, only quite recently that it has been brought into what can be called a commercial shape.

Very many of you are doubtless aware of the fact, that something over a year ago I was commissioned by Mr. George Westinghouse, Jr., of Pittsburg, now the president of the Westinghouse Electric Co., to go over to Europe and make an examination of the induction system, and, if found advisable, to purchase some of the leading inventions in that line for use in this country. Mr. Westinghouse had already made some promising experiments with the system, and had become much interested in it. So I went to London in January, 1886, and there had the pleasure of seeing an installation of some 2,500 lights working on the Gaulard and Gibbs system, at that time the only important installation which had been made. I saw at once that there were great possibilities in the system, although it was not by any means worked out practically, as our electricians would work it out in this country; but nevertheless, I was so well satisfied with the results already attained and in respect to the possible results which we could get when we put our young men in this country on it, that I closed the purchase of the Gaulard and Gibbs rights for the United States. Until within a year past the matter does not seem to have attracted any general attention in this country, but within a few months a great deal of work has been done, and it certainly seems now to have a great future before it. Theoretically it is without doubt a system of the utmost interest. There are many novel points in it—novel I mean in the sense that they have not hitherto been worked out practically. The principle of the action of the induction coil is to-day a profound mystery to a great many electrical people, and I must confess it is not any too well understood even by the best of us. My own work in connection with the subject has not been at all of a practical character; in fact, I have scarcely had an opportunity during the past year to examine any of the practical installations that have been put in, of which there are now quite a number.

Dr. Otto A. Moses—What I have to say on this subject is not of a very profound character. I have only investigated it for the last few months. I considered it in its scientific aspect for some time, and when making studies in electricity it is but natural that one should be led to the question of induction. There was one thing I would like to say that was suggested to me by the action of the light a few minutes ago. (Laughter. A short time previous to Dr Moses' remarks, there had occurred a violent blink in the incandescent lamps used in the meeting room.) I would not have stood in the shoes of the man who was in charge of the station where that thing occurred for something handsome. He is in a profuse perspiration at the present moment. There is a man in that Pearl street station in his shirt sleeves tugging away at a brush about that wide (illustrating). There is a stream of fire about that long (illustrating) from it, and there is a general gathering of the hive; all the hands are down on that dynamo floor, which is shaking now like the inside of a rolling mill, or where trip-hammers are going, and they are trying by every effort of will in the world to stop the trouble. They do not dare to put their hands on it, because if they were to attempt to stop that sparking at the commutator at this particular moment, they would have flashes everywhere, and they would be very heavy. That is the weak point down there, and it seemed to come very fortunately for us, just to show what the advantage is of a secondary distribution. In the secondary system at present, electricity is distributed in alternating currents. An alternating current machine does all that sort of working inside of it. The production and distribution of alternating currents is so simple a matter that the very first dynamo machine ever made was constructed on that principle. I recollect when Comte du Moncel told me of the consternation with which the people who were interested in the Alliance machine came to him one day and said "The thing won't decompose water"—for which purpose it was being made. "Well," he said, "I don't see any other way to do than to make it decompose water by turning it into a machine with currents of one direction, but if it were my affair I would leave it an alternating machine. Why not use the current at once for making light, instead of decomposing water with it in order to get light from the recomposition of its elements?" It was a very unfortunate thing that the alternating current machine did not decompose water, because we would have been about 20 years further in advance in the application of electrical science. That was the quietus of the alternating current machine for the time being. Well, they made a continuous current machine that decomposed water; but soon found they could make light a great deal cheaper by that alternating current machine than by combining hydrogen and oxygen. The first alternating current machine they made I have seen working near Havre in the lighthouse. It has never been stopped but once, and that was in order to put in a pillow block. No accident has happened to it, and it has been going on beautifully ever since. It was put in in 1862 or 1863, I think. But it was a cumbersome machine; however, it was as smooth running and as strong as anything possibly can be. Now, the alternating current machine is so simple that it is a wonder to me that it did not continue in general use. But then there came another matter to give it a set back. M. Archereau, discovered that a solenoid was a very excellent means of regulating a lamp. You could not use the alternating current with that. Therefore, the whole stream of invention ran into the channel of continuous current machines, and from that moment continuous current machines were universally studied because they could operate the regulating device of the ordinary solenoid arc lamp; and as the arc light business was the great one by which electricity was going to be built up as the power for general use, practical continuous current machines were invented and generally adopted. Now, when a thing once gets on the ways, sliding down like a 10,000 ton ship, you cannot stop it. It is bound to go, and when everybody's mind gets to acting in a given direction, it is bound to go on on that route.

The invention of the Jablochkoff candle gave another stimulus to the alternating current machine; but popular prejudice, excited by the death of a careless sailor on a Russian royal yacht, caused its almost total abandonment for use in electric lighting; and finally, the introduction of incandescent lighting on a great scale on continuous current circuits made it disappear entirely from use. But now the alternating current machine has taken a new and grand departure, because we find that you can only distribute currents by secondary generators when they are alternating in their character. Therefore, the alternating current machine has to be introduced. Now, the consequence is, that the alternating current machine is found to possess great advantages that were hidden, simply because they were not exploited in the beginning. They are coming now to the front, and it will be the machine for all distribution of electrical power. That sounds like a pretty broad statement when we know that motors are to be run on continuous currents. But what is the difficulty if you have got an alternating current machine that sends its currents to and fro? Why, usually you send it to and fro through the same point. You can send it *to* here and you can send it *fro* there, and you can have all the continuous current you please on the one side, and all the continuous current you please on the other side. So that an alternating current machine can be made a continuous current one. Therefore, you can apply the alternating current machine to any of the uses to which a continuous current machine is now applied.

Now, to come to the point, I would say that the practical application of this thing has been demonstrated to my satisfaction, and that it means to me a good deal. I think that alternating currents used for secondary generators are going to drive out all the small appliances for the distribution of power that are now used. We are going to have from that secondary generation a revolution. It is going to result finally in a commercial revolution. We will find currents distributed abroad in every direction, in every house, and we will have power at command for all purposes, just as we have it here at this moment in the incandescent lights around us; and that is all going to come about through this alternating distribution. I was in Pittsburgh the other day and saw this thing working, and it was very gratifying to one who has been through a good many of the mills of experiment. I had seen the first work done in incandescent lighting, and I knew what the difficulties were, and how long it took to overcome them. One insurmountable difficulty, the distribution of that light by continuous currents over great areas, still exists; for the rapid increase in the size and weight of the conductors is a bar to the extension of the system of distribution beyond a narrow limit, where large quantities of current of low potential are used.

There is in Milan, Italy, a very large system of distribution of electric light, supplying some six or seven thousand incandescent lamps of this kind, from a central station. One of the owners and originators of that plant was Prof. Colombo. You may have met that able gentleman when he was here. He came to study the distribution in the city of New York, and he was so well pleased with it that he went back to Milan and started a successful central station there. He was subsequently appointed a commissioner at the Turin electrical exhibition, when he was called upon to make an investigation of this very Gaulard and Gibbs matter; and although he was deeply interested in the central station there—the Edison central station—he, in a published paper, admitted that the method of distribution of currents of 100 volts potential was limited to an area of about 500 meters radius. In a great city that amounts to limiting it to such a degree that it is impracticable. All the influences in Paris that could be brought to bear to cause a central station to be established within its walls were ineffectual. That shows that continuous currents with an electromotive force of 100 volts and thereabouts can only be used for distributing power or for lighting purposes within very small areas.

Digitized by Google

Now, Prof. Colombo went further—although it was really against his own interest to say so; but as one of the commissioners of the exhibition he was called upon to make a report, and he made it. He said that the Gaulard and Gibbs system was going to solve the question of the bringing of power to a distribution in a city. That is, to solve the question of electrical distribution you have to combine the bringing of alternating currents there, and distributing them at lower potentials. He did not say anything about how you were going to transform the currents from alternating to continuous. He did say it was desirable to do it; he said it was a very necessary thing to be done. I add his reason by saying that he saw it was a necessary thing to save a good many of the eggs that he had in that basket. Well, that was a statement from a man whose entire interests were in other directions. Now, that is a very good way, by the bye, to judge of the value of an opinion. I heard it once said, by a lawyer who was also a judge, that the true way to find out what a man's merit was, to see what his enemies gave him credit for, because that he must have. Now, in this particular case, the merit of the Gaulard and Gibbs matter has been fully recognized by Prof. Colombo (one of the best authorities in Europe) as the thing that is going to bring the current from outside a city to points within it for low potential distribution. I go a step further, and say, I do not see why it may not get there and then distribute itself, changing itself, without the intermediation of a machine, at the door of the consumer, into perfectly safe currents, as is done by the Westinghouse system of electrical distribution.

Captain O. E. Michaelis—I have very little to say. It happens that I am living at a place where some few friends of mine conceived the idea of starting an electric light installation ; and because they had an idea that as I knew something about guns and equipment I must know something about electricity, they spoke to me about it, and I thought it was time that I tried to learn something about it myself. You know that Marryatt has written a book called "Japhet in Search of His Father," and I might write a book called "Michaelis in Search of an Electric Light." I think it might be worth reading. I have a great many friends in the Institute, all agreeable gentlemen, and I thought I would see my friends first. They treated me very kindly ; took me to the Astor House, Delmonico's, Cable's, etc., and I began to get bewildered. All the lights were good and I did not know what to advise.

In the course of my wanderings I struck a little hill town not a thousand miles from here, with not quite 5,000 inhabitants. I was provided with half a dozen letters to the electricians of the place. I arrived there one Sunday afternoon. Unfortunately the gentlemen to whom I had letters were absent. I hobnobbed with one of the men of the town whom I met at the hotel. We were searching for the same thing. It was not an electric light, however, in this case. We became acquainted and I found that he was one of the stockholders in the electric light company of the place He took me to his store and opened it, and I spent a couple of hours with him, and I obtained a good deal of information that I thought would be of interest to my friends at home, and I think it has proved so. Now, this little town is way up in the hills ; there is not a single prevailing industry in the place. It is a little country town. I arrived there Sunday afternoon at 4 o'clock, and the first thing that struck me was that the town was peculiarly lighted up. It was the first experience I had of this peculiar illuminant. It was natural gas. I asked my friend what he paid for this light? He said 50 cents a month. I said electricity cannot compete with that. I asked him if they had any gas there? He said that they had a gas company that had been charging $3 a thousand, but they had put it down to $1.90 since this new light had come in. I said, what have you got in the way of electricity? He then showed me the electric lighting. He took me to their station, and I was much struck by it. It was a business looking place. There wasn't anything that was not needed, and everything that was required was in in its proper place. I said: "What did this cost you?" He told me they had formed a lighting company with a capital of $15,000. They had a 600 or 650 light plant. They had purchased the ground on which the building stood and had paid all their expenses and had just about exhausted their capital. It was a sort of co-partnership ; all the lights were subscribed for. The large room at the hotel, where we met originally, which I suppose was perhaps 40x40 feet, was well lighted with 6 16 candle-power lamps. I went to other places and was delighted with the illumination. One man using the electric light would say, "I do not use this light as much as others do," and they would charge him so much less. I calculated that the average commercial light was sold for $8 per year per lamp. That gave them an income of $5,000. I footed up the cost of their service and expenses, and I found it to amount to about $2,000 a year. I must, however, say that the coal was very cheap. They were only paying 4 cents a bushel for it. Now, this gentleman not being an electrician, I must confess that you cannot rely upon his figures, you know, but they had made, according to his figures, about 20 per cent. on their capital. Now, I do not want to advertise any company ; I do not even like to say where this place was, but I think, Mr. President, that this is a matter which is encouraging to all electric light companies. Perhaps it was a fortunate accident for this special company that it had its plant there. I have no objection to telling you that the town was the city of Greensburgh, in the mountains of Pennsylvania, and that the company that put in the plant was the Westinghouse Electric Company, of Pittsburg.

Prof. Elihu Thomson—Mr. President and Gentlemen—This is the first opportunity I have had of meeting the members of the Institute, and I am very glad that I came down. On former occasions I have been entirely too busy and pre-engaged to make it convenient to leave the place where we carry on most of our operations.

The subject for discussion this evening is one of very great and growing importance. I am forced to recall a little experiment I made in illustration of the reversibility of an induction coil, before the Franklin Institute, of Philadelphia, in 1877. I then gave a course of lectures on electricity, and the main principle put forth was that electricity of all kinds and characters—statical, dynamical, or whatever you choose to name it, was really the same thing and of exactly the same nature, differing only in potential—pressure or electromotive force—and volume. I exhibited, of course, in illustration of this, Rhumkorff's coil, and while preparing the lecture, it struck me that it would be a very pretty experiment if I could reverse the process, and instead of getting discharges which would have the statical properties, I should take my Leyden jars and put the Leyden jar discharge through the fine wire of the Rhumkorff and see what I would get in the primary circuit. This I did, and I was somewhat astonished at the volume of current which seemed to come out of the primary. I expected, of course, to get a heavy current. I knew perfectly well that the Rhumkorff coil must be reversible, but I was surprised to see the energy that the Leyden jar discharge displayed when it was turned into what was then called the quantity current: the ends of the primary wire being brought together, there was a bright green flash, and after repeating the experiment once or twice the wires actually stuck firmly together. It was with difficulty that I separated them. They bent a little, and with a good pull they separated. There was a sufficient proof of the reversibility of the induction coil. The capacity of the Leyden jars was three gallons. The spark which fused the coil was an inch and a quarter long. Another fact came out in the experiment which was very striking. We are all familiar with the loud snap produced by the Leyden jar discharge and the bright flash. I was surprised to see, however, that the spark which struck through the coil was exactly like the Rhumkorff spark. It occupied a time. It didn't go with that sudden energy with which the Leyden jar discharged, but it went through with the appearance of the ordinary Rhumkorff spark. This thinning out was no doubt due to the retardation which occurred in that discharge. That is, a portion of the current started out first, for we must in that case call the Leyden jar discharge a current, even though it may last a billionth of a second. It passed through, as I say, in the character of a Rhumkorff spark, and the primary current seemed also to last for the same length of time. This experiment was repeated, and the primary wire was also connected with a galvanometer of very coarse wire, and the needle went right up solidly to the stop at every Leyden jar discharge. At that time, I thought it must be perfectly well known to anybody that would dwell upon the conditions.

This experiment left its impression on my mind, and my recent experiments in welding by electricity are really the outgrowth, as I see it, of that little experiment of the Leyden jar discharge sent through the Rhumkorff coil.

When engaged in electric lighting I found it necessary in the construction of dynamos to make good joints on wire, and it was with some difficulty that really good joints were made. Our wire in the early days was only obtainable in about 50-pound lengths of copper, and some of our wires required about 300 pounds, so that we had to make some 5 to 6 joints in every coil. This necessitated, of course, great care on the part of the man making the joints, and he was oftentimes liable to make slips which would not even allow the wire to be bent to and fro. In thinking the matter over, it struck me that electricity would do that work, but the thing was to get the currents. They were necessarily enormous. They were necessarily much larger than we had been accustomed to deal with. Probably no electric light currents used in those days in any case gave more than 500 amperes. The machinery had not been developed to a much further extent than that. The induction coil experiment, however, seemed to point out the way, and I designed at that time an apparatus which I thought would answer the purpose, but I was compelled to lay the business away, having no time to develop it further. Taking it up at last, however, I tried the experiment of building a small alternating machine and connecting it to a coil of moderately fine wire, which was to be the primary, and taking a very coarse and heavy secondary, so that the potential of the currents generated in the secondary might not exceed one or two volts at the most, but could run up to thousands of amperes. The first experiments made with the apparatus were entirely successful in joining

Digitized by Google

copper, iron, steel, etc., the wires being of moderate size, of course. I mention these facts simply to show their connection with the subject under discussion. We have there probably the extremest case of what we call conversion from high potential to low potential.

Dr. Moses has mentioned the fact that no commutators are needed on the alternator, and I can say that it was really fortunate for us in welding operations that there are none, because our currents are varied enormously in a very short time. We start out with a piece of metal that probably has only a few square mils in section, and with the same apparatus, we run up to an inch or more in diameter, and if we had a commutator on the machine we, of course, would have to make a new adjustment each time, and every time the current changed greatly it would be very likely to tear out the metal and throw it around, because we run under strong conditions while we are putting on the heaviest gushes of current.

As to the distribution of incandescent lights by the induction coil, I may say, that in the latter part of 1878 and 1879, in company with Prof. Houston, I made some experiments with the design of using a little arc lamp for distribution. It is called a vibrating lamp. The electrodes were vibrated to and from each other, and we used induction coils to give the impulses to vibrate the carbons and also to supply the currents to the little lamps. The incandescent lamp in those days was unknown. There was no such thing as incandescent lamps in 1878, at the time the experiment was made; but gradually the incandescent lamp became known, and induction began to attract some notice in regard to distribution. Now, it always has appeared to me that there never could be any doubts as to the efficiency of a good induction coil; that is, that the losses in an induction coil never could amount to a great deal, if it were properly made. What is a dynamo machine but an induction coil after all? It is a revolving induction coil. We have what might be called the primary circuit in the field magnets, in the magnetism, but instead of reversing the current in the field magnets we reverse the position of the secondary, that is we turn it over to get our impulse. If we turn over a portion of the armature by degrees we get a continuous even flow of current, and if the dynamo can be made to go to an efficiency of 90 per cent., why cannot an induction coil be made to go to an efficiency of 95 per cent? We use a reverse primary. We do not reverse the position of our armature in relation to the magnetic field developed by the field magnets, but we make our field magnets reverse and divide them up by laminations or by making them of fine iron wire; put plenty of iron in the coil and the losses should not be any more in making the conversion, so far as Foucault currents or local currents in the iron are concerned, than they are in a well constructed laminated armature.

In regard to the use of alternating currents, let us see if there is any possible objection to the use of them. There has been a great prejudice against alternating currents, which I think has gradually been removed on account of the very fact that they alternate, and that they are thought to offer danger of severe shocks. We have learned to look upon alternating currents, somehow, with considerable dread on account of the fact that the current goes this way and that. I had some early experience in that respect. Most of you probably have heard of the Jablochkoff light in which the induction coil was used to throw discharges over a piece of kaolin, only the discharges were of high potential, produced by low potential currents. The electrodes were drawn over the kaolin and a very pretty light, of a moderate intensity, was produced. It was in experimenting on this subject that I managed to get hold of the ends of the induction coil. To say that I was surprised would not express the conditions at all. Prof. Houston, who was present, said that I jumped into the air about three feet, and in doing so I broke away from the wires, but for a moment I felt that if the thing continued a few seconds there would be no more of me. I did not feel it anywhere but in my head, and it seemed as if a thousand corkscrews had been sent in from all sides to mix up matters internally. However, the wires were not very strong and I got away very easily. The shock was probably severe, but the potential was such that the discharge could jump through three-eighths of an inch of clear air, and the wire of the induction coil was not so very fine but that considerable current could flow. The potential was enormous. Now, the other day, in experimenting with alternating currents in which the maximum difference of potential existing was about 1,300 volts, capable of equaling in potential a good circuit of arc lamps, I happened to touch a post and to bring my hand to another post and I felt something rather queer and drew away. The result was I got a little blister on the hand, but that was all. If I had short-circuited an arc current of the same power I would not have got away so easily. I should have come away with my hand very badly burned. But as it was, the alternating current did not follow just as I ruptured the contact. That is a feature of the alternating currents which is very good in rendering them safe. Let us see if we can find any reason for it. The alternating currents rise and they come down and they reverse and so on; but there is a line along the middle of the curve which is neutral. Now, unless the materials are of very high volatility, the spark formed is very apt to be extinguished on that reversing point. And there is another fact which would cause that arc to be extinguished, which is that the effects of self-induction or extra currents in prolonging the discharge are eliminated. It would seem from these considerations that we need not have any great fear of the danger arising from alternating currents. It is very doubtful indeed whether the fluctuations in the arc light current are not quite as great, and whether the injury to a person short-circuiting an arc light current is not due as much to abrupt changes in the current as to the mere current itself,—that is, an arc light current does not usually have the character of an even wave, a smooth wave,—there are segments in the commutator acting like so many break pieces, and whatever effect they produce is effected in inconceivably short spaces of time, and if we could map the wave so produced it would be seen to be very irregular and jerky. Every one has tried the effect of a shock from a magneto-electric machine, and knows that if the field is regular and the contacts are good he can stand a pretty fair shock; but let it be irregular, let some faulty condition occur and give him a shock and then ease up a little and give him some more and it will be found to be very exhausting indeed. In the one case he knows what to expect and is prepared for it; in the other he is not. This brings us up to the consideration of the nature of the alternating current itself. It is a rhythmic wave, and it can be made so perfect and smooth that at any portion of the wave the change of current is very slight. There need be no sudden jump of current. Let us see whether we have any facts which would lead us to think that there is a difference of that kind between the ordinary arc light and the alternating current. In studying the use of alternating currents, it occurred to us there might be some difficulty in running lines on account of interference with telephones. Injunctions might be served on anybody running lines if the alternating currents had a bad effect on the telephone lines. To test that matter we ran parallel lines to the arc light circuit, using about the same strength of current on each, and I was surprised at the results. The alternating current line did not give us any induction in the telephone, while we had fifty feet or more parallel, and the arc light current gave us strong induction—a rattling, scraping sound; and when I thought of it, it all seemed very clear. At every segment of the commutator of the arc dynamo there was a little break. A difference was produced in the telephone circuit, so sudden that it was bound to produce a wave that would shake the diaphragm—a kind of scratching, irregular sound, nothing melodious about it. Then we arranged the conditions so that we could get induction from the alternating current alone to the telephone, by increasing the length and coiling the wire a little, and gradually we could hear the hum of the alternator; but it was music compared to the other. It was a musical tone; you could talk through it and not be bothered by it in the least. It is doubtful, as one of our men suggested, whether we could not, in case we had difficulty, play a tune; that is, we could send chords over the line by sending impulses the right way, so as to make everybody happy. I do not say that all alternating currents are of that character; but I do think that there is no difficulty whatever in constructing machines that will give waves that are very easy, regular and just as perfect as the waves produced by a fine tuning-fork, without any abrupt changes. I have no doubt that in the construction of alternating current machines, in which there are irregular changes in the magnetic circuits quickly effected, that the impulses would be harsh and rough. But if these changes are smooth and gradual, there is no reason why the sound produced in telephones by induction should not be very smooth and melodious, rather than disagreeable.

The President—I am sure we have all listened with a great deal of pleasure and profit to the remarks of Prof. Thomson, and although it is not exactly in the line of the subject we are discussing this evening, I am sure that we are more than pleased to hear something about the origin of his remarkably interesting discovery of the method of welding metals by electricity. I happened to be in England at the time that Prof. Thomson's discovery was announced. A cable despatch of ten or fifteen words was published, which created a most unusual excitement among the electrical and metallurgical people over there, and although upon sober second thought, some of them have since discovered that "it is not true," and others that "everybody knew it before," I assure you that very little of that was heard the first week.

One point to which Professor Thomson has called attention, the similarity between the principle of the induction coil and that of the dynamo, and which he has illustrated so beautifully, needs to be better understood than it is. The induction coil, as he has shown us, is nothing in the world but a stationary dynamo, in which the magnetic poles are moved within the mass of the iron core instead of the iron being moved in mass, carrying the poles with it: and, therefore, it seems very plain, as he has shown us, that we ought to get a higher percentage of efficiency from a well designed inductorium than is possible from the most perfectly constructed dynamo; because all the mechanical difficulties that are encountered in arranging for the free rotation

Digitized by Google

of the armature are eliminated. We can bring the reactive parts in closer physical relation with each other, and in that way increase the percentage efficiency.

In regard to one other remark made by Prof. Thomson in respect to inductive interferences with the telephone systems, I was told, in London, that the inductive lighting circuit was originally about six miles in length, a large square loop embracing perhaps eight or ten city blocks, or more, and the commotion that it created in the telephone exchanges in that region was something frightful. Injunctions were applied for, and there was a great row. Finally, as the result of considerable discussion on the subject, the circuit was re-arranged in the form of a double loop; that is, the loop was formed into a crescent shape, the wire out and back being carried on the same supports all the way. This change immediately removed the disturbance; you cannot hear it in any of the telephones in London, although some of the lines go through the same neighborhood. The fact is that the currents of the direct and return circuits seem to neutralize each other, or at all events they are effectually neutralized. The inductive disturbance does not interfere with the telephone. We would be pleased to hear Mr. Wetzler on this subject.

Mr. Wetzler—I do not know, Mr. President and gentlemen, that I can enlighten you much on this subject. But it strikes me that the point of utilizing a high potential current of low quantity for the purpose of facilitating distribution is one which may be looked upon in another light; that is to say, we may use a continuous current and interrupt it. That system has been brought out recently, and seems to present some quite interesting points. The arc current to-day may be considered in that light. We have there the conditions of a high potential circuit with low quantity. Why may we not by suitable apparatus break that current at certain points, utilize it to put our secondary generators in operation, and then continue it on; or, if you will, break it directly at a central station and use the broken continuous current (if you might so call it) in the same way as you would the alternating current? That system has been brought out recently and presents some considerations worthy of notice.

We have all heard of the advantages, and also of some disadvantages of the secondary generator system in this country, as presented here. It may interest the members to hear the opinions of some foreign electricians on the subject. Dr. Moses has given us Prof. Colombo's opinion, which is very favorable; and I think, for the sake of discussion, that some of the unfavorable opinions might be brought forward. In a pamphlet recently issued by the Siemenses, of Berlin, they flatly deny the utility of the secondary generator system. They say, in effect, that isolated installations, even large ones, are practicable on this system, as witness some of the installations already existing in Europe. These they consider, however, only isolated systems, though on a large scale. For a general distribution they claim that the thing is not feasible, in fact, is not as good as the ordinary two-wire direct distribution. However, they premise that all distribution must be done by underground conductors. They say that if you want to distribute generally, an overhead system will not do the business; that there are too many uncertainties in connection with it, and that you must go underground. Now they figure up that to put underground a high potential system, in which instead of using 100 volts ordinarily you use 2,000 volts, with a corresponding reduction in copper, the money you save, and interest, on that copper will not make a difference of one per cent. in your expenses; that the copper in the underground conductors is but a portion of the cost; that the insulation required will cost as much as the copper, no matter what the size of your conductor is; and that what you gain in conductor you will lose in insulator. They bring out the usual argument against the alternating current as not available for motors, the use of which they regard an important consideration in electrical distribution. How far these objections are good or how far they can be removed remains to be seen. I think they can be removed, if they are not removed already. But such are the opinions of Siemens, which have some weight, whatever his motives may be. He also says that you cannot regulate your secondary generator within the limits necessary to give satisfactory incandescent lighting. He says that secondary generators cannot regulate closer than four per cent when turning on all the lights, and that that is not sufficiently close. I believe that objection can be removed if it exists.

The President—I would say in respect to one point raised by Mr. Siemens, that it is not quite clear to me, since a secondary generator is in fact nothing more than a dynamo, why it is not possible to regulate as closely with a generator as it is with the dynamo in direct distribution.

Mr. Wetzler—Siemens in his pamphlet criticises other systems, but he says that he has got something that *will* regulate the secondary generator.

Mr. Mailloux—There is one point in Prof. Thomson's remarks which interested me very much; that is the analogy between the dynamo-electric machine and the induction coil. In the discussion of secondary transformers before the Electrical Society at the last meeting, I dwelt rather at length on that point. It is undoubtedly true that ideally considered the dynamo electric machine is an instrument for producing alternating currents; that we only reverse them by means of a commutator. In the dynamo we employ mechanical energy and it gives us back electrical energy. At the electrical exhibition in 1884, I remember seeing an apparatus designed by Prof. Thomson. It was a dynamo-electric machine, in which there were two armatures; one of the armatures was wound with wire capable of standing the arc light current, and it had a commutator; the other armature had small collectors. There we have what I call a first-class analogue of the induction coil, because we take electrical energy of high potential and we transform it into electrical energy of low potential. Now, considering the analogy just stated, we readily see that we are taking energy of one potential from the arc light circuit and transforming it into energy of a lower potential, but of greater volume, and in each case the amount of energy converted can be estimated by the ratio of the electromotive forces.

Prof. Thomson states that the efficiency of a dynamo being as high as 90 per cent., there is no reason why we should not have even a higher efficiency in the induction coil. That is true. In the secondary generator or transformer, we have no dead wire. In a dynamo there is always some wire which is dead at the ends of the armature, or inside of it, where it is not subjected to the action of lines of force. In an induction coil, on the contrary, every particle of the wire is placed in a magnetic field, and necessarily we must have a greater efficiency of transformation.

With regard to effects upon telephone lines, the remarks of Prof. Thomson bring to mind very interesting facts in connection with the Van Rysselberghe telegraph and telephone system in Europe. Mr. Van Rysselberghe endeavors to prevent induction in telephonic lines by subjecting the electric impulses of telegraph lines to a process by which they become undulatory; he gives them that rhythm which Prof. Thomson alludes to, and when he has done so he finds that they become powerless to produce induction on telephone lines. The facts are well known; and to-day, in Europe, the Van Rysselberghe system is very extensively used on telegraph wires, and the impulses of telegraphy, which are sharp and abrupt, are so modified by introducing condensers and coils, or equivalents, that they assume this harmonic form, so that they become incapable of producing any disturbing effect on the telephone; the telephonic impulses can be superposed over them and reproduce articulate speech.

One important point with regard to secondary generators has not been alluded to this evening, namely, the static effects which may arise. We see at once that a transformer is composed of conductors and a dielectric. If we consider the secondary as merely a certain amount of surface, with the circuit open we have in effect two large surfaces brought into close proximity to each other, but separated by a dielectric. Remembering that the charge of a condenser varies with the electromotive force into the capacity, it seems quite plain that even a very small capacity would be able to give rise to very large static charges. It is true that we reverse the impulses of the dynamo, and that the reversals take place so quickly that the process of charging, which requires a certain amount of time, will not have time to take place fully. When the subject was first discussed in Europe there was some apprehension in this regard, and I have heard that in some installations, I do not know whether in this country or in Europe, it had been found in practice that static sparks could be drawn from transformers. This feature certainly demands investigation, and if it should prove to be at all an evil, a remedy must be provided for it. I understand that Prof. Thomson has anticipated this problem, and he may have suggested a remedy.

Prof. Thomson—In regard to the efficiency of the wire of the induction coil, I may say that it is certainly possible to produce a higher electromotive force in a wire subject to induction than it is possible to produce in a dynamo armature. It is practically a greater speed that does it; that is, the alternation may be made at various rates; we can have 10,000 alternations per minute or we can have 15,000 or 20,000, and it would naturally result, if the field of the induction coil should be changed 20,000 times and to the same degree, that the wire should give out in the secondary —a certain length of wire should give out—twice the electromotive force that it would when subjected to 10,000 alternations, and also that the primary wire should kick back, as we may say, with a double kick, or in other words, be able to hold back an electromotive force twice as great.

(Prof. Thomson here made a diagrammatic sketch of a transformer on the blackboard.)

The question arises: Is the secondary wire in the magnetic field? It is not; that is a certain fact. The magnetic field is around it and does not show any polarity whatever, and the secondary wire is not in the field; but the secondary wire *was* in the field at the moment that the magnetization was going on. Consequently, the secondary wire gives out a current when the primary wire is beginning to take the current and up to the maximum which it may reach.

Now, what will be the effect, if we pass a current through this primary wire? It will cause circular magnetism around it,

Digitized by Google

and that circular magnetism will emanate in all directions quickly, and stop when it reaches the best medium, that is, when it gets into the iron. That is my view of the action. I do not know that it has been adopted at all; but I look at it in that way; that the wire conveying a current gives out, as it were, shells of magnetism rapidly expanding to large dimensions. But if they meet with such a good atmosphere as iron, they condense themselves in the iron. What does the secondary do? If it has an open circuit it does nothing. If it has a closed circuit it develops a current. I say when it has an open circuit it does nothing; I am not strictly correct there. It develops only an electromotive force in the two ends, which, if it gets a circuit will produce a current. But the very fact of the passage of the current in the secondary tends to produce just the opposite magnetization; that is, the secondary tends to produce an opposing field of its own. But if the primary is much the stronger, the secondary has no chance to have any field of its own, and it kicks all the harder for that reason; that is, it gives out more current just because it cannot have its own way.

Now, what have we in the alternating current? We have an increasing positive current from zero up to maximum, then down to the zero, and then negative to a similar maximum, and so on throughout. What useful voltage shall we assign to that current? Shall it be the maximum difference of potential? Or the average difference? It is evident that in running an incandescent lamp the average E. M. F. is the effective voltage, and not the extreme E. M. F. With a 75 volt lamp on an alternating current, the maximum difference of potential required is probably nearer 150 volts. We have an instant during an alternation when the potential is zero. We must then take the average and that is the effective voltage. This gives us another view of the electromotive force developed in a coil.

In relation to the static charge, I do not attach very much importance to that, for the reason that the actual amount of condensing surface in the induction coil is not great after all. It is possible that with induction coils working hundreds of lights, there might be a stinging shock obtained by touching the wire of the induction coil. The static charge does certainly exist; but it represents very little current, so that a person may take it without any danger. A person standing on an insulated stool can have 10-inch sparks drawn from him and he does not mind it at all. He can charge his body to a potential of many thousands of volts and he can discharge that potential from his knuckle without any other feeling than a little shock in the arm. It may benumb you a little but it does not amount to anything. As to another source of danger, in the use of induction coils, such an accident as this may happen at any time—by moisture or by faulty construction or some other such cause, the primary may become connected with the secondary or be so close to it as to cause a leak from one to the other. No particular danger should result from that alone, although there would be a more vigorous discharge, statical in character from such a connected secondary, because on the one side you would have a rather long line, and at this one point you would be able to get the discharge of your whole line in rapid succession; but the chief danger in such a case is the formation of a second contact to ground. The secondary coil which had a contact to the primary would necessarily take the potential of the line. Now, a person may go to the lamp under those conditions and his fixture might be near a metal object, it might be connected by moisture, he might stand on the moist floor and the result would be the current would come down through his body and he would be subjected to the full potential, and there is no doubt that if he should be foolish enough to stay there he would have to stay there until somebody took him away. But a man when he is shocked generally drops away from the thing that shocks him; but he may be, as we term it, hung up: that is, he cannot let go, and that is undoubtedly the reason why accidents happen in arc light distribution. If a man can get away at once, even such a potential as 2,000 or 3,000 volts will not kill him, as we have had plenty of experience to prove. To avoid such dangers in alternating current lines we provide a very simple means. We ground our secondary. If the insulation between the primary and secondary is as good as it ought to be at all times, the grounding of the secondary will not hurt anytning, that is certain. What then occurs? If the man takes hold of the secondary wire and touches a radiator connected with the ground, or a water pipe, he is already shunted by a good conductor and he cannot get anything to hurt him. That addition to the system would save us from all shocks; but it would introduce another element of irregularity and danger; that is, it would provoke contacts to the secondary line; but if a contact does occur, cut your line off altogether by putting a fusible plug in the circuit leading to the primary, so that if there is any diversion of current through to the secondary and to ground, the plug will blow out. There is another danger, of course, in having this ground connection and that is the danger of atmospheric discharges. That can be avoided by making the insulation heavy, and putting near the primary line where it enters the building, or at any convenient point, an ordinary lightning arrester. Of course it would be necessary in running such a system to test it for grounds just as lines are tested to-day.

Mr. Wm. L. Church—My proper office here would naturally be to defend the secondary system, the converter system, against attack; but I find there has been no serious objection raised; in fact there seems to be a unanimity of sentiment in favor of it, insomuch that it seems to me if we were placed in series we might generate 4,000 or 5,000 volts electromotive force in the way of commendation of the system. With reference to the opinion of Dr. Siemens I have only to say this, that I would reply to his criticisms by subscribing my fair share toward paying his passage to this country to see the thing done. I was recently at Daly's theatre and witnessed that charming production of Shakespeare's "Taming of the Shrew," and heard Petruchio insist that the moon was shining when in fact it was the sun; and it strikes me as absurd—if I may be allowed to couple that term with so distinguished a man as Dr. Siemens—to state that secondary converters will not regulate well enough for practical use, whilst the company with which I am associated is operating these converters commercially, deriving their pay from the plants, and the whole thing is reduced to an ordinary matter of fact. The variation is not appreciable by any observations that we can bring to bear upon it outside of the laboratory. We are putting in 100 volts and taking out better than 98 in selling them to people and getting our pay for them. I contend that the final touchstone in the eyes of the practical men and, more important, in the eyes of the man to whom we sell is,—can I take this thing, disregarding the whyness and simply secure the result and put it in my vest pocket?

The question has been raised as to whether the distribution upon this high potential system by underground circuits might not be in practice as costly as upon the ordinary multiple arc plan. Let us look at it from the commercial standpoint. Reduction in quantity of copper is not the sole element of economy. In fact I think there has been an injustice done to the secondary system by insisting that its prime usefulness lay in the reduction of the first cost of primary wiring. That is one way to put it. The use of the converter system—high potential system—permits the running of wires on a very small percentage of drop. With the ordinary multiple arc system and low potential, the quantity of copper required is so great that we have to sacrifice 10 or 15 per cent. of drop to secure a reasonable cost of copper; while the converter system enables us to run upon a two per cent. loss in the mains, and that saving is a merchantable article in some form anyway you figure it up; you may sell it to a customer and put the dollar in your pocket.

I might drift along, touching upon many points which are in no sense scientific, and yet seem to me to carry much weight if we consider the question in its practical and every day aspect. I am pleased to say that so far as our work has progressed—and we are treating it entirely on a commercial basis—there has seemed to result no serious difficulty.

Prof. Thomson has alluded to one other feature of the system. He states that one of the characteristics of certain forms of broken current is that they discourage your moral nature entirely, by the intermittent and very sudden and unexpected changes they take on; while on the contrary, the peculilarly rhythmic and wavy motion of the alternating current is a tranquilizer, and the alternating machine may therefore be said to be a moral agent. I have noticed the effects upon my own moral nature, and I confess I was unable to account for it until this moment.

Mr. Ralph W. Pope—One of the objects of the Institute, I presume, is to do justice to all the systems, and as the lighting system which is affording us radiance this evening has furnished a text for two or three of the speakers on account of its winking and blinking, I might say in explanation, that this particular plant is operated by a dynamo in the building. But that is not the point I wished to bring to your notice. This scene of revelry has now continued to such a late hour that the dynamo in the building is not equal to the emergency. Through foresight of this state of things, earlier in the evening the lighting was switched to the central station system, and this switching operation caused the blinking which we saw.

Dr. Moses—I stand corrected.

Dr. Moses made further interesting comments on features of the discussion, illustrating by blackboard sketches, and recalling striking points in Faraday's experiments in induction.

Mr. Elias T. Ries—It has been stated by Prof. Thomson that the alternating current that he used, on account of its undulatory character, had no effect on the telephone wires running parallel with it. I should like Prof. Thomson to please inform us what the potential of the alternating current was. If those undulations had no effect, would not the slight undulations of the telephone current itself be still less effective in causing the diaphragm to respond to them? Another point,—it has been stated by Mr. Pope, in referring to an English electric light system using secondary generators, that the disturbing effects upon neighboring telephone wires was eliminated when the main lines, out and back, were run parallel and close together, the incoming currents neutralizing the outgoing currents to such an extent that

Digitized by Google

their effect upon the telephone and telegraph lines was not noticed practically. If that is the case, is it to be assumed that on such a circuit the interruptions, the alternating impulses, will reduce their mutal efficiency, or is such reduction only effective with respect to the surrounding telephone and telegraph wire?

The President—Perhaps I had better show by diagram the arrangement of the wires in London. (Making a sketch on blackboard and explaining.)

In the original arrangement the main wire ran through the district, taking in points on one side and back to the central station through points on the other side, the convertors being in series, that is, the circuit described an irregular figure enclosing the district. In the new arrangement the out and in wires are near together throughout, in fact are on the same poles or fixtures. The telephone lines ran in all directions. The wires were in all cases put on top of the building. Although they do not have any overhead system in London, this lighting system is all overhead. The present arrangement is found not to interfere with the telephone service. The Westinghouse company had a line at Pittsburg some two miles long or more, which went on the same poles as the telephone lines.

Mr. A. P. Wright—At Plainfield I have no trouble. I cross my lines at every third pole. I started at Plainfield to put in the old system of direct current, and Mr. Westinghouse came to me one day and told me to remove my machines and install the alternating system. I knew nothing of that system at the time. We put up there a 650 light machine, and we have now wired the business portion of the town. We have running at present some 450 lights. I went down to Pittsburg and was there for two days, and saw a thousand lights running three miles from the factory. I returned, and two months after that I had my station in order. I started there with green men. When I was ready I signaled to the engineer to start, watched my volt-meter and went out to look at my lights. They were all right, and since that time we have had no trouble whatever with our machines. We started on the 1st of February. With regard to the variation in potential due to different loads on the converter, I had a little experience. In one case I had one converter working independently, and I had wired on that 53 lights in one store and 16 in another. This was on a side street and I had no means of connecting it up with the other sets of converters. The 53 lights were not intended to be on at the same time, but when we started, the people at the store naturally played with the thing a great deal. I happened to be in the store at one time and I noticed a little change in the light when a large number of lights were turned off. I could see a change and I drew the attention of others to it, but they did not perceive it. It was not perceptible to the uninitiated; I was looking for it and saw it. It was a 50-light converter, and it was sometimes running 60 lights for a few moments. As far as regulation is concerned, we require no regulation in our station to speak of. When a large load is taken off we vary the current from our exciter a little, but there never is so much load taken off at one time as to affect that very materially. We take readings about every fifteen minutes; that seems to be about as often as is necessary. We have had no trouble with the armature. It has been running now since the first of February, 15 hours a day on an average.

Mr. S. S. Wheeler—I am not sure that I understand what Dr. Siemens' objection is, but from what Mr. Wetzler says—that the system would not regulate within four per cent. I imagine that he means that when the load of lamps is increased, the increase of current would cause a loss of potential in the coil. If that is the only difficulty, I do not see why that cannot be overcome. These converter coils seem to work very well indeed, and I do not see why they cannot be handled in just the same way as the dynamo is handled. If they won't regulate, why cannot they be made to regulate? For instance, if the loss is due to increasing the number of lamps why not turn on more coil as more lamps are turned on, or why could not a differential wiring be used?

Mr. Church—In reading the reports of the Electric Light Convention at Philadelphia, I noticed statements to the effect that we had been burning out armatures rapidly. My partner, Mr. Kerr, replied very properly that it made no difference whether that was so or not—that it was an incident of construction. But the fact is that out of the entire complement of stations we have running, we burnt our first armature last week. We do not exactly know what it was due to. But the meter was reading some 65 amperes on a machine calculated to give but 45, and there was a short circuit somewhere that was taking an immense amount of current and the armature, of course, gradually heated up. The people on the circuit knew nothing about it. That was the first burnt out armature outside of our own experimental work in the shop. We have ripped out four armatures by simple mechanical contact. The wires got in contact with the field poles and were simply stripped off from the armature without the slightest burning—purely a mechanical action. A statement was also made that we were suffering enormously from the short life of the converters. The truth is that we burnt our first converter about ten days or two weeks ago.

Mr. Martin—I would like to ask Mr. Wright in regard to the distribution of these converters. My friend Duncan in Pittsburg, is very well pleased with a secondary generator plant there, and stated to the Convention that he had some of his converters on the poles, but stated that in some cases he did not think it necessary to have them there but attached them to the buildings.

Mr. Wright—At present my converters are on the poles. My lighting is scattered. They are sometimes about four or five poles apart, a great deal depending upon the disposition of the lighting. Of course I may have occasion to place my converters in the interiors of buildings in some cases, but generally outside the build ings. I propose in Plainfield, in the residence portion of the town, to run my branches from the sub mains into the central portions of the blocks.

I may mention that I am running the lamps that are in the station at 104 volts. My lights out on the circuit are well up to candle-power with 104 volts in the station. In fact people tell me my lights are over candle-power. At present I am regulating simply by my station lights.

Mr. Ries—Are the primary coils of the transformers connected in parallel?

Mr. Wright—In parallel.

Mr. Ries—And you find the regulation for that reason better; the parallel connection tends to facilitate the regulation?

Mr. Wright—Certainly. Although it is not generally intended to connect the secondaries, I should do so in the business portion of the town.

Mr. Mailloux—I would like to have somebody tell me whether anything has been done to develop the application of the secondary transformers for distributing power in motors. Dr. Moses has told us that he could send one impulse *to* and the other *fro* from the same machine. It would be interesting to know whether this to and fro matter is only theoretical or whether it is practical and has been accomplished. I would also like to enquire whether in the event of a system of distribution by periodic impulses of one polarity on each circuit, the size of the transformer, and to a certain extent the method of its application, would not need to be changed to conform to the different manner in which the energy would be distributed, because we shall have energy being supplied by the circuit for only half the time, and of the energy so supplied we must store enough in the induction coil to maintain the supplies during the other half. In other words, it must produce a certain magnetic reaction which will be sufficient to keep up the energy during the remaining half.

I would also like to know what has been found in practice to be the difference in efficiency between coil of the ordinary straight description and those of circular form, which are generally used for distributing. I have had this question submitted to me lately on several occasions, and I was of the opinion that the difference in efficiency would not exceed 2 or 3 per cent. I would like to know whether any such data have been obtained from practice.

The President—I think that the point raised by Mr. Mailloux, was pretty thoroughly investigated by Prof. Ferraris. His conclusion was something like this—that there was no particular difference in the co-efficient of efficiency, but that a good deal less amount of iron and copper was required to do the work with the closed core than with the open one.

Mr. Mansfield—The subject of the distribution of electricity for lighting purposes, by means of the converters, has been pretty well handled; but I fail to see the commercial advantage of the converter. In the installation at Plainfield, we have not such a great distance to annihilate, and all men who are engaged in the transmission of power are talking about annihilating space. I do not see that there would be any economy over the direct system, unless you go to a distance when you want your alternating currents or your high potentials so as to annihilate the distance. You use your converters or transformers to get the electromotive force down to a working basis. With motors, I presume the same converters can be used. When I first started in the electrical field, which was only a short time ago, I heard Dr. Moses speak in the most glowing terms of placing some sort of an electrical machine in the bottom of a coal mine in the wilds of Pennsylvania and transmitting the energy to New York and utilizing it for our lights. I thought that was a grand scheme. But of late I have had to figure somewhat on transmitting energy to a distance, and I met in connection with that an exceedingly practical man. He asked me if I could transmit to any distance any amount of energy. I said Yes. He wanted to know how far. I told him any distance he wanted, and he specified 25 miles, and he went a little higher and I thought I would keep on as high as he did. Finally he got to a certain point where he smiled and asked me if I was aware of a method of transmitting energy which was tied up. Well, I did not just see what he meant, and I said No. He then spoke of the great railroad systems which we have now, and that set me thinking, and I went home and commenced to figure, and from the census reports found that the cost for transporting a ton of freight on the great railroads was only about 7 mills per ton mile. Well, you can easily figure from that basis that a railroad will be a formidable rival if you go up to 25 or 50 miles. People can transmit the coal from one place to another, burn the coal in their furnaces

Digitized by Google

and produce their energy through steam much more cheaply than we could by electricity.

Mr. Mailloux—How about water power? If there is a natural source of energy, how are you going to get that to a distant town?

Mr. Mansfield—The natural sources of energy in this country are to a certain extent mythical. If you will consult the census reports you will see that there is not so much water lying around loose as some people think, and that the Lowell mills and the Lawrence mills and the Paterson mills and the mills at Holyoke have steam engines. In my opinion a station established with the ordinary arc light potential in the middle of New York city, exactly in the centre of the longitudinal axis of the island, would quite easily handle the motor problem in the entire city, and at even a less potential than they are using on some of the arc light circuits. After all, perhaps, in the arc light circuit we motor men have a means for carrying on our business without interpolating converters.

Prof. Thomson—In regard to the economy of wiring, I think that you may say that taking high potentials and distributing in multiple arc, there is a point just there. In an arc light circuit we have to take the whole current *all around* the circuit; that is the wire must be large enough to carry with a small loss the whole current to the end of the circuit which may be 5 miles away and back again.

In a multiple arc circuit at high potential, part of the energy is given out at a short distance; we do not carry that portion any further. The amount of copper needed will be very much less to carry the same energy than on an arc light circuit. Take it at equivalent electromotive force and assume that your work is done over a district pretty evenly, and you are delivering, say, energy equal to 10 h. p. at a block or two away; that energy has not to be included in the current which is traversing the whole line, it is dropped right there. Now, the energy which goes further is carried by the current, and so it goes; so that there is really an actual saving of wire, a considerable saving over the wire used on an arc light circuit.

In regard to induction effects on neighboring wires I may say that a double wire going out and returning is almost a necessity in the running of arc lights. Almost all arc light circuits go and return on the same poles, and the nearer the outgoing and returning wires are placed the better it will be. But as we cannot place them close together, we can do the next best thing—we can interchange their positions—cross and recross back. All that we have to do is to produce such a condition in the wiring as will not give an effective magnetic field which can act on other wires, or if we do get magnetic fields which will get on the other wires, we must use opposing ones.

With the alternating current machine you can turn up and down a lamp without a loss of energy amounting to anything. Now that seems a surprising fact, but it is true, The lamp may be run just as you would a gas burner; turn it down so that the filament is red, by a little attachment no bigger than my fist. It is simply the interposition of a very little coil—not an induction coil—sheathed in iron, and the capability of putting more or less wire into the circuit, in other words putting a counter electromotive force in the circuit. It will obstruct the current going through the lamp, and will do that not as a resistance in the lamp, but by throwing the electromotive force back on itself. That can be done to a single lamp or it can be done to a group of lamps.

With continuous current circuits there has been and is a continual strain after high voltage lamps. It is almost regarded as impracticable to run any distance unless you use 100 or 110 volt lamps, the highest that can be commercially made. The reason is, that when you get beyond that, the filament will almost sag by its own weight, and the 100 volt lamps that are made to-day are generally of a low efficiency, compared to lamps of lower voltage which will give exactly the same life. A 50 volt lamp, for example, can be made to use less energy than a 100 volt lamp, and give the same light.

Mr. Wright—About three watts, or even less, as compared to four.

Prof. Thomson—But when you get much below three watts you sacrifice life considerably.

In regard to the regulation, a station operating on a continuous current system over any distance has a drop which will amount to probably 10, 15 and sometimes even 20 per cent., and that is the case especially where the object is to save wire and where the fuel is pretty cheap, and where the heavy losses can be afforded. On the alternating current system the drop can be made certainly very much less on the line. The drop in the induction coil itself is altogether within our control; at least so it appears to me. The high work which is obtained from the wiring makes the resistance of the wire bear such a small proportion to the actual electromotive force at work and to the resistance of the circuit on which it operates, that there is a practical regulation. The local line, of course, can be wired so as to give very little drop without involving the use of a great deal of copper.

As to the motor question, I think that the alternating current motors can be made to run nearly as efficiently as continuous current motors, and with the saving of drop in the mains we can afford to run them less efficiently. It is not absolutely necessary to change the high potential current by an induction coil for the motor. If the motor is built to stand the potential in the main circuit, there is no need of reducing the potential.

Mr. Church—Except as a matter of personal safety.

Prof. Thomson—That is all. But it seems to me that as the alternating current motor is an apparatus that has no commutator, the machine may be boxed up and run with fair safety. The only difficulty about running motors is getting them started. The fact is that if the impulses come at a certain rate, unless the motor takes that impulse at the same rate, it will not start; that is, you must give it the speed first; you must put it in tune with the circuit by giving it the speed; then clap on the current and it will run at that speed absolutely. If you overload it you will draw it down and it will stop. Now, I have in my possession a little machine which, put on an alternating current circuit, will start from the state of rest and run right up developing considerable power. That machine may not be as efficient as the alternating current motor is, but I can put that little motor on the same shaft with the larger motor, and give it the speed of that little motor; I have the whole thing under my control. I am not at liberty to describe in full that arrangement. As yet it is not fully developed, but I hope before long to have it in such shape that it can be fully discussed. (Adjourned.)

LONG-DISTANCE TELEPHONY.

At a recent meeting of the Paris Society of Civil Engineers, M. Berthon read a paper on this subject, and gave some interesting figures with regard to silicon bronze. This material was employed for the double line between Paris and Brussels, which cost £4,000, being at the rate of about £20 per mile of double wire of 118 mils. diameter. According to M. Berthon, this bronze has a conductivity varying from 97 to 99 per cent., and a breaking strain of 75 kilometers per square millimeter, which is about 29 tons per square inch. Pure copper has a breaking strain of 28 kilometers, or 18 tons per square inch; but a special silicon bronze is made, in which the breaking strain rises to about 73 tons per square inch. In this case, however, mechanical strength is obtained at a sacrifice of conductivity, the latter being only 20 per cent. of that of pure copper. M. Berthon is not in favor of the Van Rysselberghe system of using ordinary telegraph wires for telephonic communications, because of the large number of anti-induction apparatus which would be required on lines which run alongside of railways, and he thinks it would be on the whole cheaper to establish separate double telephone circuits, arranged spirally, and of fairly low resistance. He is of opinion that with silicon bronze wires 5 mm. (197 mils. diameter) it will be possible to speak to a distance of 950 miles. It is interesting to contrast with this opinion, which, of course, only refers to aerial lines, the theory of telephone cables elaborated by Dr. Wietlisbach, of Berne, and recently published in our contemporary, *The Elektrotechnische Rundschau*. After alluding to the work of Kirchhoff, dealing with the theory of the flow of electricity in submarine cables, and pointing out that the formulæ are not applicable for short telephone cables, the author gives a formula of his own, which represents the current at one end of a cable if the E. M. F. at the other end varies harmonically. It would lead us too far to follow the author in his mathematical investigation, and we will, therefore, only point out that he arrives at the practical result that the distances to which it is possible to speak depend on the product of capacity (in microfarads) and resistance (in ohms), a point which was also very clearly explained by Mr. W. H. Preece during the discussion on Professor S. P. Thompson's paper on telephonic investigations, recently read at the Society of Telegraph Engineers and Electricians. The investigations of Dr. Wietlisbach are of practical interest, because he applies them to a particular form of telephone cable made by Felten & Guilleaume, which is extensively used in Germany. This cable contains 27 wires, each having a resistance of 45 ohms per kilometer, and .24 microfarad capacity. He determines,

Digitized by Google

first, the length of cable for which the intensity of musical sounds is reduced by half, and he finds that for

100	vibrations	per	second,	this length is	33 kilometers.
500	"	"	"	14	"
1,000	"	"	"	10	"
2,000	"	"	"	7.4	"

Assuming 350 vibrations as the fundamental note of the human voice, and making allowance for the over tones, he finds that the transmission of speech by means of this cable is excellent at one kilometer, good at five kilometers, somewhat difficult at 10 kilometers, and impossible at 15 kilometers. The limit to which speech can be transmitted by this cable, placed underground, is, therefore, about six miles. In order to apply his investigation to different cables, it is only necessary to translate the distance given above into the product, capacity and resistance, and thus we find that for 100 microfarad ohms the transmission is excellent, for 300 it is good, for 1,000 difficult, and for 2,500 impossible. As a practical confirmation of Dr. Wietlisbach's theory, it may be interesting to note that in Copenhagen, speech is transmitted perfectly well through telephone cables a little under five miles long. These have 23 ohms resistance and .19 microfarad capacity per kilometer.—*Industries.*

OBITUARY.

DANIEL DAVIS.

On Tuesday, March 22d., 1887, there died at Princeton, Mass., one, who forty years ago was far ahead of his time as a professional electrician and electro-mechanician. This was Mr. Daniel Davis, who was for many years a manufacturer of and dealer in electrical apparatus at 428 Washington street, Boston.

He was born in Princeton, March 8th, 1813. He made much of the earliest telegraph apparatus for Morse, and in his shop also was made one of the earliest sewing machines. The business which he organized is still carried on in Boston by Thomas Hall.

The principal claim of Daniel Davis, to the gratitude of our profession is, however, his treatise on magnetism. This was entitled, "A Manual of Magnetism, including Galvanism, Magnetism, Electro-Magnetism, Electro-Dynamics, Magneto Electricity, and Thermo Electricity," and was published with some 180 original illustrations. The first edition came out in 1842; but it ran through several editions, and is now out of print. Though originally published more to advertise the wares of Mr. Davis, and as a means of calling attention to his business, than as a text book of electro-technics; its value as a *vade-mecum* of electrical information was at once seen, and it appeared that he had builded better than he knew. The first edition of 1842, and the second edition which was published in 1847, were both written under the supervision of Drs. John Bacon, Jr. and William F. Channing, and hence acquired an elegance of style, and a perspicuity of language, which combined with the practical knowledge of Mr. Davis assured the success of the book; which was adopted as a text book by many colleges and high schools; becoming a great favorite especially in the United States Military Academy, at West Point, on account of the many practical demonstrations shown in its pages.

The manual is now extremely scarce and is only to be found on the shelves of second hand bookstores; but it is still highly valued by those fortunate enough to possess a copy, and even at this date many of our ablest electricians are not ashamed to confess that they have learned much from "Davis's Manual of Magnetism."

He was a friend of Charles Grafton Page, the inventor of the induction coil.

THE BALTIMORE AND OHIO TELEGRAPH CO.

The *New York Herald*, March 16th, prints the following interview with Mr. Bates, on the part of its Baltimore correspondent: "President D. H. Bates, of the Baltimore and Ohio Telegraph Co., spent the morning at the central building attending to regular routine business. Just before he left for New York city your representative had a talk with him.

"Are the New York stories true that the Baltimore and Ohio Telegraph Co. is a losing concern?" asked your representative.

"No," he replied.

"How large a business are you doing?"

"We are doing a very heavy business and are making constant additions and extensions to our system. The statement that we are falling behind and have lost a great many thousands of dollars per month have been persistently put forth by the Western Union officials, who could only guess at such things without having any actual knowledge. Their guess is wholly wrong. Since 1884 our mileage has increased three-fold, our revenue four-and-a-half-fold and our traffic nearly seven-fold. We are to-day handling a larger gross traffic than that handled by the Western Union in 1869, but at that time the mileage of the Western Union was double what ours now is, and it then cost them three times as much to perform the same service as it now costs us.

COMPARED WITH WESTERN UNION.

"Within the past three years, during which our company has been most active, the net revenue of our chief competitor has fallen $6,000,000, compared with the three years immediately preceding, while, on the other hand, it has expended during the first named period for additional wires and plant nearly as much as the whole cost of the Baltimore and Ohio telegraph system beyond the line of the Baltimore and Ohio railroad, and the fixed charges of our rival have enormously increased, reaching now the fabulous total of about $60,000,000, calculated at five and a half per cent. per annum. The Baltimore and Ohio Telegraph Co. is greater in mileage than both the Atlantic and Pacific and the American Union Telegraph companies together, which were sold to the Western Union company six years ago for $23,240,000, although they never paid their working expenses. It is twice as great as these companies were in volume of traffic and far more efficient for work.

STRONG ENOUGH.

"On the other hand the Baltimore and Ohio Telegraph Co. last year paid over to the Baltimore and Ohio Railroad Co. a large sum as clear profit on the fiscal year's operations, besides paying for all the batteries, instruments and supplies used by the Baltimore and Ohio railroad for its train service. The youngest offspring of the oldest railroad corporation in the United States, with no fixed charges, and with what I believe to be the best service and most capable staff in the world, can, therefore, be considered as solid and substantial enough to stand alone."

A MARVELOUS TELEPHONE.

Telegraphing on March 8th, the Paris correspondent of the London *Times* said:—"I was invited to be present to-day at some telephone experiments between Paris and Brussels with a new apparatus known as the 'micro-telephone push-button.' These experiments, which were made on behalf of the two telegraphic administrative departments of France and Belgium, produced a very lively impression on those present, and I believe the new apparatus to be the most perfect yet produced.

"As its name indicates, it has the form of an ordinary electric push-button. When the button has been pushed in, and has made a sound at the other extremity, it is taken out, and is found to be attached to a long electric wire. There is thus exposed the telephonic plate, which is extremely sensitive, so that where it is necessary to speak at short distances it is not necessary to come close to the instrument. For communications in the same street, or the same house, the operator places the upper part near himself, and without changing his position he can speak with the correspondent at the opposite extremity.

"But what makes this apparatus the most successful of telephonic instruments is, that it can be made for half-a-crown, that is to say, for not more than the price of the ordinary push-button. Between Paris and Brussels this instrument, costing half-a-crown, worked with admirable precision.

"The inventor is Dr. Cornelius Herz, one day nominated Grand Officer of the Legion of Honor, next day described as an emissary of Germany, and lastly as the friend, adviser, and confident of General Boulanger. He is in reality an electrician whose inventive talent has been stimulated by his residence in America, where there is a boundless demand for improvements in electrical apparatus and in all mechanical contrivances."

ELECTRIC LIGHT AND POWER.

Capt. Moses, of Sheffield, Ala., has closed a contract with the Westinghouse company to light the new city.

Chittenango, N. Y., will be lighted by electricity. Address, Luke McHenry.

An electric light plant is contemplated in Cambridge, Ohio. Address, John M. Ogler.

D. J. McCornell, John C. Anderson, and D. W. Hughes, of Chattanooga, Tenn., have purchased the Brush electric light plant and will make extensive improvements.

The Electric Light and Power Co., Knoxville, Iowa, will establish an electric plant.

Medina, N. Y., will be lighted by electricity. For further information address, Charles H. Hedley.

The Atlantic City Gas and Water Co., John Roberts, president, Atlantic City, N. J., will be lighted by electricity.

Digitized by Google

An electric plant will be established in Sparta, Wis. G. D. Dunn, and others are interested.

The People's Gas and Electric Light Co., Canton, Ill., will establish a plant.

Vinton, Iowa, will be lighted by electricity. S. H. Watson, and others, are interested.

Shenandoah, Pa., will be lighted by electricity. J. S. Kistler, and others, are interested.

Kingston, Pa., will be lighted by electricity. Q. L. Newell is interested.

An electric light plant will be established in Downington, Pa. H. B. McFarlan and S. A. Block, are interested.

Foreign.

Austria.—According to the *Neue Freie Presse* the introduction of the electric light into Vienna is not to be expected at an early date, as the conditions demanded by the municipal authorities are practically prohibitory. They stipulate that all the plant and conductors of the undertaking shall become their property, *without compensation*, if within three months after the contract has expired, and notice has been given, all such conductors, etc., are not removed and the street restored to its former good condition. The authorities further claim the power of demanding an alteration of the conductors "on any grounds whatever," and as often as they may think proper, and, further, of pointing out "defects" in the system (either according to their own judgment, or to that of experts whom they have the sole power of selecting), and of insisting on the removal of such defects within any time at their own discretion. If any damage is perceived in the roadway, or "in other objects," the contractors may be called upon to prove that it has not been occasioned by their workmen. Lastly, for the concession to lay cables into the two court theatres, they demand a yearly rate of 7,750 florins. This represents a yearly rent of 40,000 florins per kilometer for the cable to the Castle theatre, and 3,400 florins per kilometer for the opera house. How exorbitant these demands are we may judge from the fact that the Tramway company has to pay only 2,220 florins per kilometer.

Belgium.—The incandescent lamp is making steady progress in Belgium. Among recent installations of interest is the lighting of the village of Berchem, near Antwerp, and that of a new hospital at Watermael, which has been supplied with 350 lamps fed by gas engines.

Germany.—The Staedtische Elektrizitaetswerke Co., of Berlin, has completed an installation of 36 arc lamps in the Leipziger strasse, at Berlin. According to the terms of the contract entered into between the municipality and the company, the lamps are to furnish a minimum of 2,000 hours of lighting per annum, at the rate of 3d per hour per lamp, so that the annual cost will be not less than £900 per annum. This company is also making preparations for supplying incandescent lighting to a large district in the same quarter of Berlin. The cables will shortly be laid in the Spittlemarket, the Behren strasse, and the Zimmer strasse, and it is anticipated that fully 12,000 lamps will be taken up during the course of the ensuing 12 months.

Scotland.—The first step towards the introduction of the electric light into private houses, says a Glasgow contemporary, has been taken by a south-side burgh, the desired end being hastened by the notoriously bad quality of gas at present supplied by the Glasgow corporation. A city firm is at present erecting the necessary plant on the banks of the Cart to supply the inhabitants of New Cathcart and Mount Florida with the electric light. The terms are unique in their way. The rent for the use of the light is to be based on the actual quantity of gas consumed during the previous year, the receipt of the Glasgow Corporation Gas Co. being accepted. Neither more nor less than the amount on the receipt is to be paid. The erection of the necessary lines has already been commenced.

Spain.—The Spanish government find that they are now able to supply their wants in the way of electric light equipment for their war ships without going beyond their own frontiers. The lighting of the new cruisers "Numancia" and "Pilar" has been entrusted to the Sociedad Espanola de Electricidad.

New Zealand.—The antipodes seem to be fully awake to the fact of electricity being an important industrial adjunct. We notice the successful formation of a company called the "Reefton Electrical Transmission of Power and Lighting Co.," the result of some lectures and ocular demonstrations of both these branches of the modern "Hercules," by Mr. Walter Prince, an electrical engineer of considerable name in the Britain of the south for accomplished successes of both power and lighting. The company in question starts work with about 500 lamps and 60 h. p. transmission for mining work, and Mr. Prince expects to complete the works in about six months. Water power is the initial source of energy.

NEW INCORPORATIONS.

The Dodge City Electric Light and Heating Co., Dodge City, Kas. Capital stock, $50,000. Fr rick Gardner, and others, incorporators.

The Winfield Light, Heat, and Power Co., Winfield, Kas. Capital stock, $10,000. James H. Bullen, and others, incorporators.

The Edison Light and Power Co., Lacrosse, Wis. Capital stock, $150,000. G. Van Steenwyke, W. H. Holcomb, S. Y. Hyde, and others, incorporators.

The Merchants Electric Light Co., New Haven, Conn. Capital stock, $30,000. M. W. Burwell, and others, incorporators.

The Chicopee Electric Light Co., Chicopee, Mass. Capital stock, $10,000. J. W. Cumnock, and others, incorporators.

The Greenport Electric Light and Power Co., Southold, N. Y. Capital stock, $12,000. James T. Carley, and others, incorporators.

The Idaho Springs Electric Light Co., Idaho Springs, Col. Capital stock, $10,000. Albert W. Horn, and others, incorporators.

The Greensburg Electric Light Co., Greensburg, Kas. Capital stock, $100,000. C. W. Myers, and others, incorporators.

The Burdett-Loomis Gas and Electric Light Co., Chicago, Ill. Capital stock, $100,000. Joseph S. Woodruff, and others, incorporators.

The Citizens Electric Light Co., Braddock, Pa. Capital stock, $10,000. Treasurer, W. A. McDevitt.

The Mountain City Electric Light and Illuminating Co., Altoona, Pa. Capital stock, $10,000. Treasurer, E. T. Dunn.

The Northwestern Electric Light and Lighting Co., Chicago, Ill. Capital stock, $200,000. Gideon F. Lanahen, and others, incorporators.

The Lake Shore Electric Light Co., Chicago, Ill. Capital stock, $10,000. William G. Beale, and others, incorporators.

The Westfield Electric Light Co., Westfield, Ill. Capital stock, $25,000. William A. Chase, and others, incorporators.

The East River Electric Light Co., New York City, N. Y. Capital stock, $30,000. John Carroll, and others, incorporators.

The New Rochelle Electric Light Co., New Rochelle, N. Y. William R. Beryholz, and others, incorporators.

The Somerville Electric Light, Heat and Power Co., of Somerville, Mass. Capital stock, $25,000. Oren S. Knapp, and others, incorporators.

The Ann Arbor Thomson-Houston Electric Co., Ann Arbor, Mich. Capital stock, $50,000. Wilbur F. Dowdson, Port Huron, and others, incorporators.

The Trenton Gas and Electric Light Co., Trenton, Mo. Capital stock, $18,000. George Josselyn, and others, incorporators.

The Saratoga Gas and Electric Light Co., Saratoga Springs, N. Y. Capital Stock, $325,000. William Foster, Jr., and others, incorporators.

The Excelsior Electric Co., Harrisburgh, Pa. Capital stock, $40,000. Treasurer, George W. Shank, Wilkes Barre.

The Albany Edison Illuminating Co., Albany, N. Y. Capital stock, $250,000. Henry R. Pierson, and others, incorporators.

The Olney Edison Electric Light Co., Olney, Ill. Capital stock, $10,000. H. M. Hall, and others, incorporators.

The Anthony Illuminating Co , Anthony, Kas. Capital stock, $100,000. T. H. Stevens, and others, incorporators.

The Somerville Electric Light Co., Somerville, Mass. Capital stock, $20,000. Elmer H. Capen, and others, incorporators.

The Canton Electric Light and Power Co., Canton, N. Y. Capital stock, $18,000. Horace D. Sackrider, and others, incorporators.

THE MICROPHONE FOR DETECTING LEAKS.

At the recent congress of gas and water engineers, held at Eisenach, in Germany, it was stated that many German water companies had adopted the microphone as a part of the regular equipment of their turn-cocks in order to enable them to detect the presence and estimate the importance of any leakage. The microphone is fixed upon a plate which can readily be attached to a stop-cock. It is said that the presence of a leakage at the rate of only a few drops a minute can readily be detected by this means.

ELECTRICITY IN MINING.

The transactions of the Mining Institute of Scotland, vol. viii., part 8, contains a long paper by Mr. F. J. Rowan, C. E., on the applications of electricity to mining operations. The topics dealt with include those of lighting, haulage, pumping, winding and ventilation. The experiments of Marcel Deprez on the transmission of power are noticed, and the author compares the various systems of transmitting power. The paper appears to have been very ably prepared, and it is well worthy of perusal by those who are interested in mining operations. Several plates of illustrations accompany the text, amongst them being a good sectional view of the Immisch motor.

RECEPTION AND BALL OF ELECTRIC LIGHT EMPLOYES.

The employés of the Citizens' Electric Illuminating Co., Brooklyn, N. Y., will give a reception and ball at the Palace Skating Rink, Easter Monday evening, April 11th.

CORNELL UNIVERSITY.

ANNUAL INSPECTION TOUR OF THE ENGINEERING CLASSES.

As we go to press, the engineering classes of Sibley college are making their annual tour of inspection. Below is the itinerary and programme of the classes in electrical engineering:

SECTION 3.—SPECIAL PROGRAMME OF THE ELECTRICAL ENGINEERS.

Friday, March 25th.—Leave via D., L. & W. at 6.15 A. M. and proceed to Scranton, arriving at 12.25. Inspect the electric railway.

Leave Scranton at 5.20 P. M. for Carbondale. Members of the party unable to leave Ithaca as above, can take the train at 12.20 P. M., reaching Scranton at night in time to join the party for Carbondale. In the evening inspect the Westinghouse station and system of electric lighting.

Saturday, March 26th.—Leave Carbondale at 7 A. M. and Scranton at 8.30 for New York city.

Sunday, March 27th.—In New York city.

Monday, March 28th.—Go to Newark, by either the Pennsylvania or the Morris and Essex Railroad, about 8 A. M. At Newark, visit the United States Electric Lighting company's works, Mr. Edward Weston's laboratory, and, if time permits, the establishment of the Callendar Waterproofing and Insulating Company.

Evening.—Visit one of the United States company's electric lighting stations in New York.

Tuesday, March 29th.—Leave the Grand Central station, 42d street and 4th avenue, at 8 A. M. for Yonkers, inspecting Field's electric motors, and the Eickemeyer dynamo, leaving on the return at 11.30 A. M., and dining in New York.

P. M.—Visit the Stevens Institute of Technology, at Hoboken.

Wednesday, March 30th —The party will report at the Edison offices, 65 5th avenue, at 10 o'clock, and visit the various establishments and factories of the Edison company, and offices of the Electrical Accumulator Company.

Thursday, March 31st.—Visit the Western Union building, in New York city, in the morning, and the American Electric Manufacturing company's works in the afternoon, 163 West 13th street.

Friday, April 1st.—Leave the Grand Central station, at 9 A. M., for Ansonia via Bridgeport, Conn., to inspect the works of Messrs. Wallace & Sons. Returning, leave Ansonia at 3.25 P. M. and reach New York at 6 P. M., in time to reach Hoboken, and then take the night train for Ithaca at 7.15 P. M.

QUARTERLY REPORT OF THE WESTERN UNION TELEGRAPH COMPANY.

FOR THE QUARTER ENDING MARCH 31, 1887.

Executive Office,
Western Union Telegraph Co.,
New York, March 9, 1887.

The following statement will show the condition of the company at the close of the quarter ended December 31st, 1886:—

Surplus October 1st, 1886, as per last quarterly report		$5,324,261 98
Net revenues, quarter ended December 31st, 1886		991,018 00
		$6,315,279 98
From which deducting for—		
Interest on bonded debt	$123,469 70	
Sinking funds	20,000 00	
		$143,469 70
Left a surplus January 1st 1887, of		$6,171,810 28
The net revenues of the quarter ending March 31st instant, based upon nearly completed returns for January, partial returns for February, and estimating the business for March, will be about		$ 750,000 00
Add surplus, January 1st, as above		6,171,810 28
		$6,921,810 28
From which appropriating for—		
Interest on bonds	$123,470 00	
Sinking funds	20,000 00	$143,470 00
Leaves a balance of		$6,778,340 28

There has been a large increase over the corresponding quarter of the previous year, in the volume of business, and a handsome increase in gross revenues from the land line service, which was counterbalanced by loss of revenues from cable service and by increased expenses incident to the greater number of messages handled, and for extensive reconstructions.

The outlay for extensions, additional wires and for insulated wires, with a view of getting the wires off the poles in New York and Brooklyn, has been very large; and must continue for a time to absorb a large part of the net earnings.

The committee recommend that no dividend be declared.

Respectfully submitted,

NORVIN GREEN, *President.*

SUIT FOR INFRINGEMENT OF THE GAULARD AND GIBBS PATENT.

The Westinghouse Electric Company entered suit against the Sun Electric Company, of Portland, Me., March 15th, in the United States Circuit Court, at Boston. The suit is based upon alleged infringement by the defendant company in the State of Massachusetts, of the Gaulard & Gibbs' patent, of October 26, 1886, upon distribution by secondary generators. Order of notice was made returnable April 4th. The Sun Electric Company is alleged to be doing business in Woburn, Mass.

STORAGE BATTERY LITIGATION.

The Electrical Accumulator Company, of New York, has entered in the United States Circuit Court, at Cleveland, Ohio, two suits, which are practically one in aim, against the Brush Electric Company for alleged infringement of patent. The New York company sues upon patents of Camille A. Faure.

MANUFACTURING AND TRADE NOTES.

The Page Belting Co., Concord, N. H., send out, as a companion to their very handsome and complete catalogue, a pamphlet entitled "The Kinds and Grades of Belting to Use for Different Kinds of Work." Its contents should be very useful to purchasers of belts. The proper selection of belting, not only as to quality, but as to width and thickness, is often but illy considered in workshops. The information and suggestions of the Page Belting Co.'s pamphlet are clearly in the interest of efficiency and economy, and therefore to the advantage of purchasers. Their catalogue is supplemented by a comprehensive telegraph cypher code for the use of customers in ordering.

The Clark Dynamo is exhibited in practical operation at 508 West 14th street, New York, every afternoon from 3 to 5 o'clock. All who are interested in dynamo-electricity are invited to call and see it.

The B. F. Goodrich Co., Akron, Ohio, are manufacturing hard rubber goods, and announce their readiness to supply any specialties required in electrical work.

LEGAL NOTES.

U. S. COURT.—SOUTHERN DISTRICT OF NEW YORK.

SNYDER *et al* v. BUNNELL *et al.*

Decided November 11, 1886.

1. CONTRIBUTORY INFRINGEMENT.

When a person makes and puts on the market an article which of necessity and to the knowledge of such person is to be used for the purpose of infringing a patent, such person will be held liable under the doctrine of contributory infringement.

2. LIABILITY AS INFRINGER.

But the doctrine that a party may be held liable as an infringer solely because an article sold by him might be used by the purchaser as one element of a patented combination would be too dangerous to be upheld,

3. PROOF OF CONTRIBUTORY INFRINGEMENT.

In order to hold a party liable under the doctrine or contributory infringement, there must be proof that what he did was for the purpose and with the intent of aiding infringement. (*Saxe* v. *Hammond*, 1 Holmes, 456.)

Mr. G. G. Frelinghuysen and *Mr. A. C. Farnham*, for the complainants.

Mr. H. H. Morse and *Mr. C. C. Leeds*, for the defendants.

COXE, *J.*:

The defendants are charged with infringement of letters patent No. 103,383, granted to James P. Snyder for an improvement in electro-magnetic burglar alarm apparatus. The invention consists in an arrangement for setting in action automatically a secondary circuit, which will continue the alarm, although the circuit first set in action may be suddenly stopped again by the shutting of the door or window.

The claim is as follows:—

An alarm indicator arranged for automatically causing a secondary and independent circuit at the indicators by the action of the armature lever with a disc or other device, and the springs or other closing device, and a secondary line of wire, 1 B^2, connecting the battery and the magnet, all substantially as specified.

The evidence of infringement is confined to the sale by the defendants on the 17th of December, 1884, of one instrument, known as an "automatic drop," and the admission by one of the defendants that others like it had been sold by his firm.

It is conceded that this instrument may be used in connection with the other apparatus described in the patent so as to constitute an infringement. It is also conceded that it is susceptible of a perfectly innocent use. There is no proof that the defendants have ever used it in an infringing combination. There is, indeed, no direct proof that it was ever so used by any one. Certainly there is nothing to indicate that the defendants have sold an automatic drop, knowing that it was intended to be used to infringe the patent. For aught that appears, every instrument sold by them may have been used in a perfectly legitimate manner.

If the defendants were doing what the complainants charge—

Digitized by Google

namely "making and putting on the market an article which, of necessity, to their knowledge, is to be used for the purpose of infringing the complainants' patent" there would be little difficulty in holding that the complainants' rights are invaded. But it is thought that the evidence will not warrant so broad an accusation. If held liable for selling an automatic drop, it might with plausibility be urged that they are equally inculpated by the sale of a galvanic battery or an electric bell, for these are necessary adjuncts to the patented combination.

The complainants invoke the doctrine of contributory infringement, the clearest illustration of which is, perhaps, found in *Wallace* v. *Holmes* (9 Blatchf., 65). In that case the complainants had a patent for a burner in combination with a chimney. The defendants manufactured and sold the burner, leaving the purchaser to supply the chimney, without which the burner was useless. The burner could not be used without infringing the patent. All this the defendants knew. It was because of this use and this knowledge that they were held liable. (See, also, *Richardson* v. *Noyes*, 10 O. G., 501; *Bowker* v. *Dows*, 3 Ban. & A., 518: *Alabastine Co.* v. *Payne*, 27 Fed. Rep., 559; *Travers* v. *Beyer*, 26 Fed. Rep., 450; *Cotton Tie Co.* v. *Simmons*, 106 U. S. 89 S. C., 1 Sup. Ct. Rep., 52.)

In each of these cases the complainants succeeded because the article dealt in by the defendant was only useful when combined as provided by the patent in question, and was sold by him intending that it should be put to this unlawful use. A careful examination has failed to discover an authority holding a party liable as an infringer solely because an article sold by him might be used by the purchaser as one element of a patented combination. Such a doctrine would be too dangerous to be upheld. The case most nearly approximating the one in hand is *Saxe* v. *Hammond* (1 Holmes, 456), Judge Shepley there says:

> As defendants only make one element of the patented invention, in order to hold them guilty I must find proof connecting them with the infringement. Different parties may all infringe by respectively making or selling, each of them, one of the elements of a patented combination, provided those separate elements are made for the purpose and with the intent of being combined by the party having no right to combine them. But the mere manufacture of a separate element of a patented combination, unless such manufacture be proved to have been conducted for the purpose and with the intent of aiding infringement, is not in and of itself infringement.

The record upon this branch of the case is too vague and uncertain to uphold the charge of infringement. Where a necessary link is absent in the chain of evidence, it cannot be supplied by mere suspicion.

The bill is dismissed.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From February 15 to March 8th, 1887 (inclusive).

Alarms and Signals:—*Electric Burglar Alarm*, E. E. Carr, 357,815. *Electric Alarm and Signal Bell*, S. H. Short, 357,865. *Electric Fire Alarm*, W. L. Horne, 357,960. *Speaking Tube*, A. S. Fontaine, 357,589. *Electrical Signal Device*, W. Hand, M. C. Wright and F. A. Polock, 357,922, February 15. *Fire Telegraph*, J. H. Guest, 358,393. *Electric Push-Button*, A. G. Davis, 358,109. *Electrical Gas Alarm*, W. McVay, 358,161. *Electrical Mail-Indicator*, V. A. Krepps, 358,360. *Electro-Magnetic Thermoscope*, H. J. Haight, 358,350, February 22. *Thermostat*, E. W. Upton, 358,511. J. L. Campbell, 358,728. *Extension Table Call-Bell*, J. E. Johnson, 358,614. *Electric Station Indicating Apparatus*, W. L. Bundy, 358,645. *Shoal Water Alarm*, L. Frik, 358,655. *Transmitting Signal Instrument*, F. Pearce and J. Jones, 358,694, March 1. *Self-Signaling and Self-Recording Electro Magnetic Thermoscope*, H. J. Haight, 358,854. *Fire-Alarm*, F. G. Lyon, 358,864. *Electric Bell*, E. A. Wildt, 358,910. *Apparatus for Detecting Leaks in Gas Pipes*, W. W. Stern, 358,949. *Annunciator*, A. D. Blodgett, 359,051. *Electro-Magnetic Transmitting and Distributing Thermoscope*, H. J. Haight, 359,210, March 8.

Clocks:—*Electric Clock System*, T. J. Zoeller, 357,885, February 15.

Conductors, Insulators, Supports and Systems:—*Manner of Making and Cooling Joints for Electrical Conduits*, B. Williams, 358,095. *Cable Hanger*, J. A. Barrett, 358,140. *Subway Structure for City Streets*, F. N. Blanc, 358,311, February 22. *Insulating Tube for Electric Conductors*, C. L. Clarke, 358,592. *Electric Conduit*, R. L. Harris, 358,609. *Duct-Conduit for Electrical Conductors*, G. D. Holt and W. T. McGinty, 358,778, March 1.

Dynamos and Motors:—*Dynamo-Electric Generator*, J. W. Easton, 357,705, February 15. *Transmitting Gear for Electric Motors*, W. H. Knight, 358,043. *Regulator for Dynamo-Electric Machines*, F. V. Y. Graells, 358,133. *Dynamo-Electric Machine*, R. Eickemeyer, 358,340, February 22. *Electric Motor*, M. W. Long, 358,682. *Method and Apparatus for Synchronizing and Regulating the Movements of Motors*, J. H. Rogers, 358,753, March 1. *Electric Regulator*, O. B. Shallenberger, 359,101. *Armature and Process of and Apparatus for Forming the Same*, C. G. Curtis, S. S. Wheeler and F. B. Crocker, 359,205, March 8. *Oiler and Wiper for Commutators*, J. Snowberger, re-issue, 10,816, March 8.

Galvanic Batteries:—*Galvanic Battery*, W. H. Tasker and T. J. Jones, 358,087, February 22; J. B. Perreur-Lloyd, 358,464, March 1; H. J. Brewer, 359,055, L. A. W. Desruelles, 359,063, March 8. *Galvanic Cell*, W. Frishmuth, 358,030 and 358,031. *Voltaic Battery*, T. J. Jones, 358,120. *Electric Battery*, S. S. Wheeler and C. G. Curtis, 358,314 and 358,386, February 22. *Manufacture of Plates or Elements for Voltaic Batteries*, W. H. Tasker, and T. J. Jones, 357,642. *Galvanic Battery and Apparatus Connected Therewith*, A. Rene and C. W. Pridham, 357,646, February 15. *Manufacture of Plates or Elements for Voltaic Batteries*, D. J. Fitz-Gerald, 358,111. *Electric Battery Jar*, C. G. Curtis and F. B. Crocker, 358,019, February 22.

Ignition:—*Electric Gas-Lighting Apparatus*, C. B. Bosworth, 359,053, March 8.

Lamps and Appurtenances:—*Arc Lamp*, V. Klan and F. Spurny, 357,774, February 15; W. A. Crowdus and H. M. Sutton, 358,145, February 22; H. C. McDill and J. E. Gaston, 359,221, March 8. *Incandescent Lamp*, T. A. Edison, 358,599 and 358,600, March 1. *Electric Lighting System*, J. E. H. Gordon, 358,346. *Switch Board for Electric Light Systems*, G. H. Warde, 358,309. *Pump for Producing High Vacua*, E. Thomson, 358,131, February 22. *Sealing-in of Wires for Incandescent Lamps*, M. M. M. Slattery, 358,492, March 1.

Metallurgy:—*Electric Amalgamator*, T. H. Trauernicht, 358,002, February 15. *Electro-Magnetic Ore Separator*, G. W. Mansfield, 359,085, March 8.

Miscellaneous:—*Electric Heater*, W. L. Burton, 357,572. *Sanitary Galvanic Appliance*, P. H. Vander Weyde, 357,647. *Obtaining Chlorine by Electrolysis*, D. G. Fitz Gerald, 357,659. *Electric Temperature Regulator*, C. E. Lee, 357,838, February 15. *Time Check Apparatus*, J. S. Goldsmith, 358,032. *Electrical Pumping Apparatus*, M. A. and A. Michales, 358,053. *Machine for Straightening Rails*, A. J Gustin, 358,116. *Automatic Fire Extinguishing Apparatus*, E. T. Copeland, 358,336. *Armature for Electro-Magnets*, C. A. Gaiser, 358,343. *Induction Coil*, M. M. M. Slattery, 358,415. *Electrical Door Opener*, L. P. Summers, 358,417, February 22. *Regulator for Induction Coils*, M. M. M. Slattery, 358,493. *Binding Post*, G. Westinghouse, Jr., 358,518. *Electric Fluid-Pressure Engine*, same, 358,520. *Electrically-Actuated Fluid-Pressure Motor*, same, 358,521. *Electrically-Actuated Fluid-Pressure Motor and Circuits Therefor*, same, 358,713. *Electrical Apparatus for Operating Valves in Mains*, F. B. Page, 358,775. *Automatic Electric Fluid Regulator*, R. C. Page and F. H. Soden, 358,691. *Induction Coil*, M. M. M. Slattery, 358,793. *Automatic Mechanism for Straightening Railroad Rails, &c.*, A. J. Gustin, 358,810, March 1. *Automatic Valve for Regulating Fluid Pressure*, A. P. Massey, 358,866. *Machine for Separating Iron Tacks or Nails from Particles of Tin or Zinc*, A. E. Convers, 358,961. *Electric Bolt-Releasing Device*, G. L. Henzel, 358,975. *Electric Switch Register*, C. Fearon, 359,067, March 8. *Electrical Circuit*, J. F. Mehren, 357,726. *Device for Regulating the Flow of Electric Currents*, E. T. Starr, 357,873, February 15.

Railways and Appliances:—*Electric Railway*, E. M. Bentley, 359,050, March 8. *Suspended Conductor for Electric Railways*, C. J. Van Depoele, 359,512, March 1. *Electric Railway Signal*, E. D. Wells, 357,881. *Car-Brake*, G. F. Card, 357,976. *Electro-Magnetic Brake*, same, 357,576. *Circuit System for Electric Brakes*, same, 357,760, February 15. *Electro-Pneumatic Interlocking Apparatus*, G. Westinghouse, Jr., 358,519, March 1. *Electric Railway Signal*, C. D. Tisdale, 359,040, March 8.

Secondary Batteries:—*Cut-Out for Secondary Batteries*, G. B. Prescott, Jr., 357,627, February 15. *Secondary Electric Battery*, J. T. Van Gestel, 358,092. *Electrical Accumulator or Storage Battery*, C. P. Elieson, 358,341, February 22. *Secondary Battery*, W. W. Griscom, 359,072, March 8.

Telegraphs:—*Telegraphy*, R. G. Brown, 358,379, February 22: C. Selden, 358,890, March 8. *Telegraph Sounder*, R. C. Rutherford, 357,789, February 15. *Stock Indicator*, A. B. Smith, 358,896. *Telephone and Telegraph*, N. F. Palmer, 358,939, March 8.

Telephones, Systems and Apparatus:—*Telephone*, W. D. House, 358,812, March 1; N. F. Palmer, 358,940, March 8. *Telephone Transmitter*, N. F. Palmer, 358,941; J. H. Tabony, 359,188, March 8. *Telephone Switch*, J. W. McDonough and H. H. Eldred, 357,682. *Desk for Telephone Use*, C. A. Patterson, 357,687. *Multiple Switch-Board*, W. S. Ford, 357,821, February 15. *Telephone Annunciator*, J. A. Barrett, 358,250. *Telephone Exchange System*, G. L. Wiley, 358,317, February 22. *Mechanical Telephone*, C. M. Radford, 357,967; J. H. Howard, 357,995, February 15; J. S. Jones, 358,357, February 22; G. W. Lord, 359,215, 359,216, and 359,217. *Mechanical Telephone Line*, same, 359,218, March 8. *Telephone and Telegraph*, see *Telegraphs*.

OKONITE

TRADE MARK.

CHAS. A. CHEEVER, Pres. WILLARD L. CANDEE, Treas.

The Okonite Company,

MANUFACTURERS OF

Underground, Aerial and Submarine

Insulated Wires and Cables,

No. 13 Park Row, New York.

MITCHELL, VANCE & CO.,

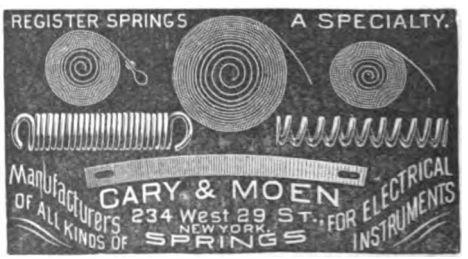
GAS FIXTURE MANUFACTURERS,

Have added a department for the Manufacture of **Electroliers** and other fixtures adaptable to any system of **Incandescent Electric Lighting,** also Combination Fixtures for both Gas and Electric Light.

Estimates and designs furnished upon application.

836 and 838 BROADWAY,

NEW YORK.



WANTED.

A gentleman well versed in Electricity desires a situation as Assistant Electrician.

Address, LAWRENCE ZIMMERMANN,

326 Manhattan Ave., Brooklyn, N. Y.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

NEW YORK, MAY, 1887.

TELEPHONE PROFITS.

IT was once jocosely remarked by a prominent inventor, that he knew of nothing equal to the storage battery as a means of developing a man's latent capacity for lying. If, instead of storage battery he had said telephone, we think that most persons familiar with the subject would be inclined to agree with him. The bill lately under consideration at Albany, for reducing the charge for telephone rentals in the state of New York, has given rise to the usual amount of unintelligent discussion, and of incoherent animadversion against the owners of the Bell telephone patents as a set of conscienceless and grasping monopolists. For example, a prominent New York journal states that it was shown at the hearing that "the American Bell Telephone Company owns the majority of the stock of all the profitable telephone companies in the state, 35 per cent. of the stock of the unprofitable companies, and receives $14 per annum from each instrument in use by all companies." The idea has been sedulously inculcated by many of the newspapers, that by far the greater portion of the total amount paid by the public for telephone service finds its way into the coffers of the parent company in the shape of patent royalties, and in this manner much adverse public opinion has been manufactured by interested parties.

These assertions, however, are by no means borne out by the facts in the case, which are accessible to any one who cares to investigate them. The seventh annual report of the American Bell company for the year ending December 31st, 1886, shows the following statements of receipts from all sources.

Rentals of telephones	$2,109,492.44
Dividends from local companies	844,555.76
All other sources	142,952.71
Total gross receipts	$3,097,000.91
Dividends paid during the year	$1,568,336.00

Number of telephones under rental, 353,518.

From this statement it appears that the average gross receipts from all sources, per telephone, is $8.56 ; that the average amount of rental per pair of telephones paid by the licensees, is $11.92, or $5.96 per instrument, and that the average amount of dividends paid by all local companies to the parent company, per telephone, is $2.39. The dividends paid by the parent company, average $8.86 for each pair of telephones under rental.

It is well known to all familiar with the telephone business, that by far the greater part of the gross receipts of the local companies is paid out for local labor, particularly for attendance at the central station, and for the repair and maintenance of lines. The Central Union company, which covers several prosperous states in the central portion of the Union, and which may, therefore, be regarded as a fair representative of the average conditions obtaining in the public telephone service, has not proved an exceptionally profitable investment. It usually paid dividends of six per cent. per annum, until the troubles in Indiana, resulting from the passage of a bill by the legislature similar to that which failed to pass in the state of New York, reduced the receipts in that state to a point which not only left no profit, but entailed a loss to be made up on the remaining territory, since which time the dividends of the company have been reduced to four per cent. Clearly the figures which we have given, by no means indicate that the public is overcharged for the benefit it receives from the telephone, considering the actual cost of maintaining the service in an efficient condition.

THE MAY MEETING OF THE INSTITUTE OF ELECTRICAL ENGINEERS.

THE Annual Meeting of the American Institute of Electrical Engineers will be held May 17th and 18th, at the house of the Society of Civil Engineers, New York.

The election of officers will take place at the evening session, May 17th. Morning and afternoon sessions will be held on the 18th, devoted chiefly to the reading of papers and discussion. At this writing the following papers are arranged for: "Novel Phenomena of Alternating Currents," by Professor Elihu Thomson. "Storage Batteries in Practice," by E. P. Roberts, of Cheyenne. "The Proper and Improper Construction of an Electric Light Plant," by J. A. Powers, of Troy. "Electric Lighting of Railway Coaches," by T. C. Martin and J. Wetzler, of New York. "A Universal Wire Gauge, by the committee of the Institute on that subject, Capt. O. E. Michaelis, chairman. "Hard-Drawn Copper Wire for Telegraph Lines," by Wm. Maver, Jr., New York. Papers are expected from Professor W. A. Anthony, of Cornell University and David Brooks, of Philadelphia, of which the subjects are not yet announced. The

Digitized by Google

meeting promises to be one of great interest. The topics announced above comprise matters that almost daily engage the attention of practicing and consulting electrical engineers at this time, and it is quite certain that the contributions whose titles are not yet announced will prove of equal significance. A large attendance of members as well as of others interested in electrical work is expected.

READERS of the *Journal of the Society of Telegraph Engineers and Electricians* (London), No. 65, Vol. xvi., will be grieved, as we have been, to note the ominous employment of rather tart and caustic personal comment in a scientific discussion before that body. The use of personal contumely, as a polemical weapon in technical debate, has heretofore, happily, been confined chiefly to theological controversies; although it was resorted to with much ferocity in the philological field during the memorable combat between Dr. Fitz Edward Hall, of the British Museum, and the late Richard Grant White, some dozen years ago, over the proper use of a few common English words. The electricians fell foul of each other upon so impersonal a topic as the theory of long-distance telephony. All will admit that occasions not infrequently arise in the *use* of telephones, over long or short distances, when weak human nature may be forgiven a moderate use of strong language; but it is difficult to discern any incitement to mutual hostility in a technical argument concerning "static capacity," "induction," "environment," etc. We are glad to be able to say that in their heated dispute Prof. Thompson and Mr. Preece, stopped far short of the billingsgate of the famous Hall-White quarrel; but we think they went sufficiently far in that direction to justify us in calling their attention to the comment of an American poet upon the results of a somewhat heated discussion in a western scientific society, to wit:

> Now I hold it is not decent for a scientific gent
> To say another is an ass,—at least to all intent;
> Nor should the individual who happens to be meant
> Reply by heaving rocks at him, to any great extent.

MEASURES for statutory regulation of the charges for telephone service have been before the Legislatures of several States during the past season, but with small success. The bill presented at Albany had a full consideration in committee. The committee investigated the subject at considerable length, having before it on several occasions representatives of the telephone companies doing business in the State as well as advocates of the measure. The telephone officials were closely questioned by the committee on facts and figures. The proposed bill was adversely reported. The matter will hardly come up again at the present session of the Legislature.

The effort to secure the repeal in Indiana of the statute regulating telephone charges after a sufficient experience of the inconvenience arising from its working, had the support of a large part of the business community; the bill passed the lower house, and would doubtless have passed the Senate, but for the wrangle over the lieutenant-governorship, which left the senators no time for anything but "politics" till the statutory limit of the session was reached.

Quite aside from the question of whether the compulsory reduction of existing rates of charge for telephone service would benefit the public—and the experience of Indiana indicates a negative—a far-reaching principle is involved in any state regulation, to which renewed attention is called in the following paragraph from the N. Y. *Evening Post*, referring to the bill at Albany:

> Any such measure is a clear violation of the patent laws of the United States, whose intent and meaning now and always have been to give to the inventor the sole and exclusive use of his invention for a limited number of years, as an inducement to further inventions and improvements, whereby civilization is advanced and human comfort and convenience are promoted and increased. This is one of the principles evolved by society in the course of ages as the most salutary for itself, and accordingly grounded in the statutes of all modern states. In the eye of the law it makes no difference whether the inventor and his assigns make much or little money during their limited time. Nobody is compelled to pay them anything. Those who do not consider a telephone instrument worth $75 per year (or $7,500, if the company choose to ask that sum) can leave it alone. Now, if the time has come for changing the principles of patent law, let them be changed by the only authority competent to undertake that task. The Constitution of the United States has expressly committed that class of subjects to Congress. Any meddling with it by State Legislatures is impertinent and revolutionary. We are not unmindful of the fact that a subordinate court in Indiana has come to a different conclusion.

THE feasibility and advantages of a union of gas and electric lighting interests are receiving increased attention and discussion on all sides. We are glad to reprint elsewhere (page 192) the paper read by Mr. George W. Graeff, Jr., of Philadelphia, at the third annual meeting of the Ohio Gas Light Association. Mr. Graeff treats his topic—"Gas and Electricity—Two Interests or One?"—comprehensively and forcibly, presenting considerations in favor of the suggested union that should appeal strongly to the financial interests of the owners of gas stocks. The question has passed the stage of discussion in many places, and has reached that of experiment. Our exchanges furnish a constantly increasing list of gas companies that have established or contracted for electric light plants.

COMPETITION in rates with the Western Union Telegraph Co. has now reached Pacific coast business. The daily journals of April 30th announce a rate of $1 for ten words between the East and the far West, made by the Postal Telegraph Co. in union with the Baltimore and Ohio Co. and the United Lines Co. Reduced rates for telegraphic money transfers are also announced.

THE electric subway bill, now before the Pennsylvania legislature, described in our Philadelphia letter, would doubtless prove a very satisfactory measure to corporations fortunate enough to secure grants under it if enacted. As described by our correspondent, it gives subway companies an unrestricted use of streets and highways, and gives little or no consideration to city, borough or private interests. It seems unlikely that the bill will be permitted to pass in its present shape.

THE public will not readily credit with disinterested zeal for the public welfare the politicians and others at Albany who are endeavoring to exclude the Comptroller and the Commissioner of Public Works from the proposed re-organized Subway Commission. Gen. Newton, not only as Commissioner of Public Works, but on account of his character, his attainments as an engineer, and his acquaintance with electrical work, is perhaps the one man in the municipal administration who can best serve the city's interests on the Commission.

WE take pleasure in mailing to subscribers the Tables of Equivalents of Measurement, prepared by Mr. Carl Hering, and published in our present issue, printed on a single sheet for the convenience of electrical engineers, and others who may have occasion to use such a table. We shall be pleased to supply copies upon application, to all who desire them.

ARTICLES.

THE SO-CALLED "DEAD WIRE" ON GRAMME ARMATURES.

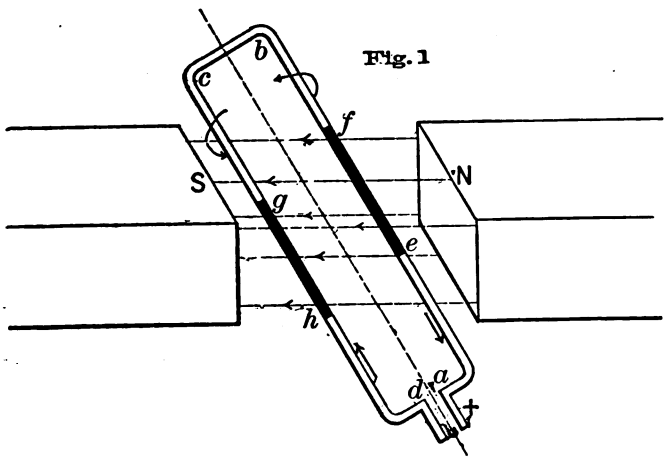
BY CARL HERING.

THE question whether the wire on the inside of the Gramme ring armature and on the ends of a cylinder armature, is active or inactive, has been discussed at great length in the last few years, but apparently without leading to any definite and indisputable conclusions. Recent publications show that some authorities still appear to believe that for some theoretical reasons the wire on the inside of a Gramme ring is as active as that on the outside. The writer has therefore made a simple and conclusive experiment which appears to prove beyond question, whether this wire is active or inactive.

The question is not one which is of interest merely from a theoretical point of view, but it bears directly on important points in the construction of machines, such for instance as placing a magnet in the inside of a Gramme ring, or making a cylinder armature of square section instead of oblong.

The two theories which explain the generation of electromotive force by moving a wire near a magnet, may be briefly summarized as follows: If a loop of wire, *a b c d* in figure 1, be revolved about its axis in a magnetic field

Fig. 1



between two opposite poles, an electromotive force will be generated in the direction as shown. The first and older theory, sometimes termed the theory of threading lines of force through a loop, explains the induction of an electromotive force, by saying that the number of lines of force which pass through this revolving loop is always either increasing or decreasing, and that this increase or decrease in the number of lines of force threaded through the loop generates electromotive force. According to the second and newer theory, generally termed the theory of cutting lines of force, an electromotive force is generated when a wire cuts lines of force; the induction therefore takes place in the two parts *e f* and *g h* of the loop *a b c d*, and only in those parts, as the remainder of the loop does not cut lines of force.

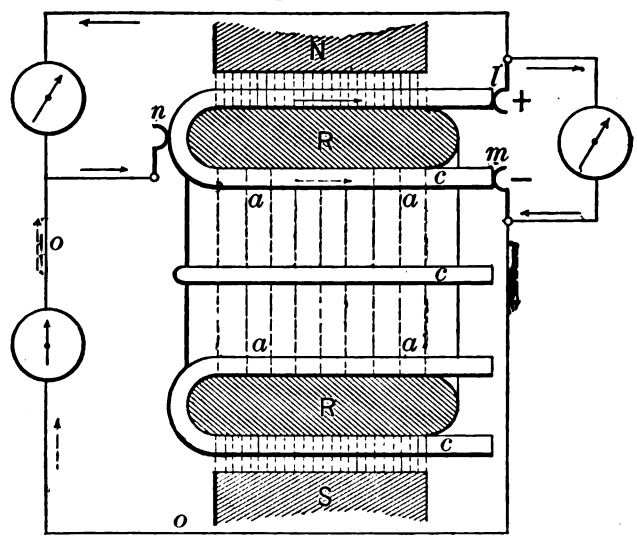
It will be seen that these theories, as stated, do not conflict, both may be, and undoubtedly are, correct as far as they go. The second theory is, however, by far the more satisfactory as it tells us precisely where the induction takes place, and where we must endeavor to place the wire of a loop or coil in order to render it active. The first theory, referring only to the loop in general, leaves us to believe that the loop must be considered as a whole, and that, therefore, all parts of the wire forming the loop are of equal importance in the generation of electromotive force, that is, they are all equally active. The theory does not state, directly, that all parts of the loop are equally active, but it leaves one to infer that this is the case; it is this interpretation of the theory which, it is claimed, proves that that part of the wire which is on the inside of the Gramme ring and on the ends of a cylinder armature is as active in the generation of electromotive force as the other parts of it.

This interpretation of the older theory necessarily conflicts with the theory of cutting lines of force; both cannot be correct. We believe that the older theory is generally interpreted in this way; if not, and if the induction is not the same in all parts of the loop, then the theory is not sufficiently complete or exact to enable us to properly design dynamos, as it does not tell us where the induction does take place. According to the older theory it is the loop *a b c d* as a whole, which generates the electromotive force, the theory does not tell us what parts, if any, of the loops are superfluous. On the other hand, the second theory states that the induction takes place in the parts *e f* and *g h*, and that the rest of the loop is useless as an inductor, it serves merely as a conductor or collector of the currents, and should, therefore, be made as short as possible.

In order to prove conclusively which of these two conflicting statements is wrong, without the use of any abstruse theoretical deductions, the writer made the following simple experiment with a view, more particularly, of finding out whether the wire on the inside of a Gramme ring was active in generating electromotive force, or whether it was mere dead resistance, acting only as a conductor.

The core of a Gramme ring was wound with a number of coils, each one consisting of only one turn of a wire, as shown in figure 2, in which R R is the core of the ring,

Fig. 2



shown in vertical cross-section; N, S, are the two poles of the field, and *c*, *c*, *c*, are three of the coils. Each coil consisting of one turn, is insulated from all the others and has its two ends, *l*, *m*, bare and not connected with any of the others; each coil has its insulation scraped off at the bend *n*. Three fixed brushes, *l*, *m*, *n*, were fastened to the frame of the machine so as to touch these three parts of each coil as it passed by them. The field was excited by another machine and the armature was made to revolve rapidly. In applying a test galvanometer to the brushes *l*, and *m*, as shown, there was a strong current flowing in the direction indicated, showing the action of one coil of a simple Gramme armature. In order to find out whether this induction took place equally in all parts of the loop or coil *l n m*, according to the older theory, or whether it took place only in that part *l n* which cuts lines of force, the test galvanometer was placed first between

Digitized by Google

the brushes *l* and *n*, indicating a current, as shown, in the same direction as before, the current indicated by it being in this case only that which was generated in the half of the loop *l n*, the other brush *m* having first been removed. The brush *l* was then removed and the galvanometer placed between the brushes *m* and *n*, in which case it indicated no current whatsoever, showing conclusively that there was no electromotive force generated by that portion (*m n*) of the loop which was in the inside of the ring. According to the older theory it ought to assist in generating the electromotive force manifested at *l* and *m*, as it forms part of the loop *l n m* through which the lines of force are threaded from the pole-piece N to the core R. The experiment, however, showed conclusively that it did not generate electromotive force, that all the current which flowed from *l* to *m* through the galvanometer was generated in the part *n l*, the other part, *n m*, acting merely as a dead resistance to conduct the current from the end *n* of the active wire to the brush *m*. According to the newer theory the part *l n* is the only portion of the loop which cuts lines of force, and should, therefore, be the only one in which induction takes place,—which the experiment has shown to be the case. The part *m n* being shielded from the magnetism by the iron R, does not cut lines of force and is, therefore, dead resistance. This, therefore, applies equally well to the wire at the ends of cylinder armatures.

This shows conclusively the correctness of the theory of cutting lines of force and the fallacy of the older theory as interpreted above. But aside from theories, it shows that, as there is no induction in the part *m n*, it is preferable to dispense with it if practicable, for instance, by bringing it around on the outside of the ring on the opposite side, thus making a cylinder armature of it, or by rendering it active by creating a field in the inside of the ring with an additional pair of pole pieces and magnets. The experiment also shows that if it were not for other reasons the best form for a cylinder armature, as far as relates to dead wire, would be to have it very long, and very small in diameter.

A second experiment was then made to still further prove the correctness of the theory of cutting lines of force. The field was made very intense so as to oversaturate the core R R, thus causing some lines of force, *a a*, to leak through the air space in the inside of the ring; such conditions no doubt often exist in Gramme armatures, the iron in the core of the ring being frequently much too small in cross-section. In again applying the test galvanometer at *l* and *m*, or at *l* and *n*, the same results as before were obtained, but on connecting it with *m* and *n*, it indicated a current in the direction shown by the dotted arrows, which is in the *reverse* direction, around the coil, to that induced in *n l*, and therefore tends to neutralize it. This is readily explained by the newer theory, as the wire *m n* cuts the lines of force *a a* and, therefore, must generate a current in the direction shown. The older theory seems to fail completely to account for this current, for, according to that theory it ought to be in the other direction. The only way to account for the current by this theory, appears to be to consider the loop as being formed by the wire *m n* and the test galvanometer circuit. But this fails to explain why the difference of potential exists at *m* and *n* when there is no galvanometer circuit, a fact which can readily be proven.

As the wire on the inside is thus shown to be dead, it might be inferred that the advantage of placing a second pole-piece and magnet in the inside would be very great, doubling the number of volts generated, as it doubles the active length of wire. But this is by no means the case, provided the machines are in both cases well proportioned. The reason is as follows. For the same armature, the number of volts generated depends only on the total number of lines of force cut, provided the speed is the same. If the armature core is saturated by the ordinary form of pole pieces, it is not possible to economically increase to any great extent the number of lines of force which enter it; a second pole-piece may be placed in the interior and will distribute the field over a larger surface of the armature, but it cannot add much more magnetism because the core, being already saturated, cannot be forced to take many more lines of force. It therefore appears that any such gain due to interior pole pieces would be limited to the cases when the armature core is not saturated by the external pole pieces. But there is apparently no reason why this case should occur, as it is always possible to saturate the small cross-section of the ring by the large pole pieces on the outside.

We are informed by good authority that the theory of cutting lines of force assumes that the number of lines of force which follow the ring from pole to pole is proportional to the area exposed to the pole pieces. We are unable however to find anywhere, such a statement as a part of this theory; on the contrary it can readily be proved that this general assumption is not correct in many cases. As long as the iron of the ring is below saturation then it is true that the induction will increase about in the same proportion as an increase in the size of the pole-piece area, provided the intensity per square inch remains the same, for it is evident that in this case the total number of lines of force, that is, the capacity of the magnets, will have to be increased proportionally. But as soon as the ring is saturated, then an increase in the size of the pole pieces (of the same intensity per square inch) will no longer increase the number of lines of force proportionally. In this case, which is the more common, the above assumption is, therefore, not correct. It is understood, of course, that if the area of the pole pieces of the same intensity be doubled for instance, the capacity of the magnets for generating the magnetism must be doubled, as there are then twice as many lines of force.

This subject of interior pole pieces was referred to in some of the writer's earlier articles[1] in which it was shown that the electromotive force will be increased proportionally with an increase in the number of lines of force passing into the core, and that these lines of force may be increased by increasing the size of the pole-piece surface of the same intensity, provided the iron in the magnetic circuit is not oversaturated, in other words if the cross-section of the iron (including the core of the armature) be increased in proportion to the number of lines of force. For instance, suppose the cross-section of the core of the armature to be doubled, and the number of lines of force entering it be doubled either by doubling the area of pole pieces of the same intensity, or by doubling the intensity and keeping the area the same, then it is evident that if the speed with which the wire passes through the field remains the same, the induction in volts will be twice as great, and as the wire is not necessarily doubled in length the induction in volts per foot will be greater than it was before.

As the small core of a Gramme ring can generally be saturated by pole pieces on the outside, the advantage of interior pole pieces must not be looked for in this direction. The chief gain seems to be in increasing the area of the non-magnetic space between the pole pieces and the armature core, and thereby diminishing materially the great magnetic resistance which this space offers to the lines of force. According to S. P. Thompson,[1] the magnetic resistance of air may be 20,000 times that of the iron, which, if correct, will show the great importance of making the magnetic resistance of this space as small as possible by increasing its area and diminishing its depth or thickness. Kapp[2] states that the magnetic resistances of air and iron (at low magnetization) are as 1440 to 2. Although this is much lower than the figure given by Thompson, it shows that it is highly improbable that it may happen that the resistance of the air space between the pole and the

1. Electrician and Electrical Engineer, 1886, pp. 301 and 369.
2. Proceedings of Society of Telegraph Engineers and Electricians, Nov. 11, 1886.

Digitized by Google

armature ring will be much less than that of the ring itself, except perhaps in abnormally proportioned machines with a very small amount or a poor quality of iron in the ring. In such poorly designed machines the advantage of interior pole pieces would be less.

This advantage of interior pole pieces, therefore, lies in the economy of the magnetism, but as this magnetism requires for its generation only from 2 to 10% of the total energy of the machine, this advantage is merely in the reduction of this small fraction.

There is a disadvantage in having an interior pole-piece which in some cases may be so great as to more than outweigh the advantages. The speed of the wire on the inside is necessarily less than that on the outside; with small thick rings this difference is very great being sometimes as great as 40 to 50%. In that case if the interior pole-piece merely re-distributes lines of force by taking some from the outside surface and leading them into the ring on the inside surface, it is evident that it will do more harm than good, as many of the lines of force will then be cut at a less speed, and therefore generate less potential.

Another disadvantage lies in the fact that the two interior pole pieces may, in the case of smaller rings, be quite near to the iron or steel shaft, in which case many of the lines of force will leak directly across from one to the other through the shaft, and as these are not cut by the wire on the armature, they are wasted.

One way of rendering the inside wire active is to place a short thick fixed magnet in the inside of the ring, the poles of which are of like polarity to those on the outside. With such a machine the following experiment might at first appear to be a convincing illustration of the great advantage of such an interior magnet, but upon closer examination the apparent advantage will be found to have been due to other causes. Let the machine be run with both external and internal magnets excited and let its output be measured. Then let another test be made but without exciting the interior magnet; it will be found to generate very much less electrical energy; thus apparently showing an advantage in favor of the interior magnet. But it will be noticed that when the interior magnet is not excited many of the lines of force from the external magnets will pass directly across the ring and through this dead magnet, which then acts as a sort of magnetic short circuit to the poles of the ring; many of the lines of force will then no longer be threaded through the coils on the ring, which will therefore generate much less potential. Or, according to the other theory, the wire on the inside will then cut lines of force which have the wrong direction, and will therefore generate a potential in the *reverse* or opposing direction similarly to the case of the wire *m n* figure 2, which, when the core is oversaturated, cuts the wasted lines of force *a a* which, having the wrong direction, generate an opposing electromotive force as shown. The output of the machine in the second case will therefore be the difference of two opposing electromotive forces. The interior magnet therefore does harm when not excited, the machine would in this case generate more potential if the magnet were removed altogether. The proper way to make such a comparative test would be to test the machine first with the interior magnet excited and then with this magnet removed altogether. Any difference may then be safely attributed to the interior magnet.

The experiment just described is only one among many which show how easy it sometimes is to mislead, by striking results, the minds of people who prefer to trust to their own powers of observation rather than to accept the opinion of a technical engineer.

PHILADELPHIA, March, 1887.

ELECTRIC RAILWAYS IN RUSSIA.

According to the Moscow *Technik* a project has been set on foot by some Belgian capitalists for the construction of a short railway in Russia to be worked by electricity, and to connect the towns of Varsovie, Wilanow, Mokotow and Czerniakow.

PRACTICAL NOTES CONCERNING THE CONSTRUCTION, USE AND MANAGEMENT OF STORAGE BATTERIES.[1]

BY A. RECKENZAUN.

(Continued from page 105.)

If we spread these materials upon two flat sheets of lead they will cover about 4.4 square feet each; the layer of spongy lead on one of the sheets being $\frac{5}{64}$ths of an inch deep, and that of the peroxide on the other $\frac{1}{16}$th of an inch thick. This pair of plates when immersed in a box containing acid, with their covered sides facing each other, would constitute a Faure accumulator. Unfortunately, however, the active materials will not adhere perfectly to metallic sheets, and this deficiency of good contact reduces the capacity. This explains the reason why Faure employed more than double the amount of paste for a given capacity than is being used by makers of perforated plates, for instance; but we do not at present concern ourselves about the various modes of *constructing* plates of secondary batteries, and deal only with general principles influencing the storage capacity.

(*b*) *Cells for Stationary Purposes.*

Capacity, 330 ampere hours.

Weight of peroxide in positive plates.....	15.00 lbs.
" " spongy lead in negative.....	11.25 "
Total weight of active material.....	26.25 lbs.

Capacity per pound of active material, 12.6 ampere hours.

Here we have 15 plates, 8 of which are negative, and 7 positive. There are in each plate 728 little squares offering a free surface of 131 square inches. The positive plates are approximately $\frac{5}{16}$ths of an inch thick, and the negatives $\frac{1}{8}$th; the volume of the peroxide is 91 cubic inches, and that of the spongy lead 62.5. The free surface offered by the positive plates to the acid is 6.37 square feet. These plates are much thicker, the metallic supports are correspondingly stronger, therefore altogether heavier and far more durable than those used for locomotive purposes. It appears that owing to the greater depth of active substance there is a smaller percentage of the same utilized. We may then be justified in saying that the capacity of an accumulator does not depend upon the *volume* of material alone, but also upon the mode of distributing it. No definite rules can be laid down, and we have to ascertain the best proportions for different types of plates by experiment.

ELECTROMOTIVE FORCE.

The E. M. F. due to the free hydrogen and oxygen is only 1.5 volts, but the normal E. M. F. of a lead and peroxide of lead element is 2 volts, whilst the initial force of a freshly-charged cell is as high as 2.25 volts; which, however, drops almost immediately when discharging. This higher figure is supposed to be accounted for "by the presence of ozone, which is oxygen charged with a higher energy in order to force the third atom of oxygen into the molecule." (Sprague, "Electricity.")

Gladstone and Tribe take the two volts to represent the normal E. M. F. of the arrangement of lead, peroxide of lead, and dilute sulphuric acid, and they believe that the 2.25 volts obtained at the first moment is due to hydrogen and oxygen occluded on the respective plates, and which either diffuse out, or are speedily destroyed. It will be seen hereafter that the E. M. F. varies considerably with the *rate* of discharge. When the external circuit resistance is large relatively to that of the internal resistance of the accumulator, then the E. M. F. of the latter is very constant, though not absolutely so, because the internal resistance increases gradually during the discharge as the specific gravity of the acid falls, a circumstance which

1. From the *Electrical Review*, London.

Digitized by Google

will be considered in conjunction with sulphating. Although during the discharge we obtain normally only two volts, the charging E. M. F. must always be more than 2.25 volts, since this represents the counter electromotive force of each cell when in the condition of the high activity indicated above.

There are actually two conditions regulating the charging E. M. F.; one is the counter E. M. F., which is slightly higher at the end than at the commencement, and the other the internal resistance, which, on the contrary, is least at the completion and greatest at the commencement of the charging process. These two influences partially counteract each other.

RATE OF CHARGE AND DISCHARGE.

This depends: 1, upon the free surface of the plates; 2, upon the thickness of the plates; 3, upon the efficiency aimed at; and 4, upon the E. M. F.

If a high efficiency is aimed at, then the charging must be effected at a reasonable rate, so that the gases evolved in electrolysis can be fixed by the plates almost as quickly as they are produced. Practice dictates that the economical charging rate of the thin plates (*a*) is about 4.5 amperes per square foot of peroxide in contact with the acid; and in the case of the thick plates (*b*) about 4 amperes per square foot of free surface of the positive plates.

When charging, the metallic support (grid) assists in decomposing water, hence it is usual to take the entire surface of the plates when expressing the charging rate. The actual free surface of the positive plates in the locomotive type (*a*) is 5.8 square feet, and that of the stationary type (*b*) 9.3 square feet; the relative currents to be used will, therefore, be 3 amperes in the former and 2.5 amperes per square foot in the latter. The E. M. F. required under these normal conditions averages 2.4 volts per cell. By charging at a higher rate it is possible to accomplish the process in less time, but at a sacrifice of efficiency, because we have to employ a higher E. M. F. to force the larger current through; the gases are generated too fast, whereby a larger percentage escapes in bubbles rising to the surface of the acid. Thus whilst we may use 2.5 or more volts per cell for charging, we can under no circumstances count upon more than two volts in discharging.

EFFECT OF THE RATE OF DISCHARGE UPON THE USEFUL CAPACITY AND THE E. M. F.

Tests made with cells (*a*) for locomotive purposes, with a constant external circuit resistance.

TABLE I.

Time.	Rate of discharge in amperes.	E. M. F. in volts.
9.45 a.m.	55.64	2.14
10.0 "	46.65	2.04
10.15 "	46.01	2.0
10.30 "	46.01	2.0
10.45 "	46.01	2.0
11.0 "	45.8	1.99
11.15 "	45.58	1.96
11.30 "	44.94	1.9
12.0 "	44.51	1.9
12.15 p.m.	44.51	1.9
12.30 "	42.8	1.87
12.45 "	40.66	1.87

Average rate, 45.76 amperes. Time occupied, 3 hours. Useful capacity, $45.76 \times 3 = 137.28$ ampere hours. At 1 o'clock the current dropped suddenly to 25 amperes, at 1.15 to 17 amperes, indicating that the cells were practically exhausted.

The charges and discharges were made with a series of six cells; the results of one only, however, are tabulated; this cell had been charged to its full capacity in each case. Nevertheless, table i. shows a useful capacity of only 137.28 ampere hours, against 156.38 ampere hours in table ii. At the high rate of discharge the current falls gradually, in fact it is not constant for more than three-quarters of an hour throughout the experiment; the E. M. F. likewise falls with the current, though not in the same ratio. This result indicates that the battery has been discharged at too high a rate; the combination of the gases could not take place with sufficient rapidity, and some of the energy had to be sacrificed. There are, nevertheless, numerous instances where such variations may be almost imperceptible, but where a high rate of discharge is much desired; this is the case with electric cars, boats, and the like. In table ii. the discharge is practically constant.

TABLE II.

Time.	Rate of discharge in amperes.	E. M. F. in volts.

3.0 "	22.09	1.99
3.30 "	22.09	1.96
4.0 "	20.7	1.9

Average rate, 22.34 amperes. Time occupied, 7 hours. Useful capacity, 156.38 ampere hours.

On further examination we find that the initial E. M. F. in tables i. and ii. is 2.14 volts; this lasted only a few minutes, nevertheless, it ought to be taken into account when ascertaining the *average* E. M. F. The current, again, in table i. drops suddenly from 55.64 to 46.65; this is only partially due to the drop of E. M. F., and mainly to the fact that iron tape was used as an external resistance, which got very hot in a short time; as the resistance rose with the temperature, so the current diminished. This variation is not so marked in table ii., where the current drops from 23.97 to 22.56 in the first half-hour; the same section of iron tape was used in this case, but of a length to give nearly double the resistance, and therefore about half the current.

In calculating the percentage of fall of current and of E. M. F. throughout an experiment, we ought not to take the first reading as the highest, but the second reading; because the initial effect is of little value and of but short duration. Taking the second and the last readings into account, we find that the fall of E. M. F. in table i. is .17 volt, or 8.33 per cent.; the fall of current is 5.99 amperes, or 12.83 per cent. In table ii. the differences are much less as a natural consequence of the lower rate of working; there the drop of E. M. F. is only 6.86 per cent., and of the current, 8.15 per cent. between the second and the last readings. With an average discharge of 45.76 amperes the current drops 12.83 per cent. in $2\frac{3}{4}$ hours, the external resistance being practically constant; by discharging the same accumulator at the average rate of 22.34 amperes, the current falls only 8.15 per cent. in $6\frac{3}{4}$ hours. This points to the well-known fact that a secondary battery must be discharged at a comparatively low rate if its current or E. M. F. is to be kept constant without altering the external resistance or altering the number of cells in circuit. In practice, it will be found that the most economical *current rate* is that which discharges a given accumulator in 10 hours; this holds good for stationary accumulators (*b*), but for the locomotive type (*a*) we can exceed this rate considerably without sacrificing efficiency.

ENERGY.

The energy given off by a storage battery is the product of the current and the E. M. F., and the *rate* at which energy is being given off is expressed in watts.

Digitized by Google

Reverting to table i., the rate at which energy is being consumed at 10 A. M. is 95 watts, whereas at 12.45 P. M. it falls to 76 watts. The *average rate*, however, is 45.76 amperes × 1.964 volts = 89.87 watts; and this represents .12047 electrical horse-power or 3,975.51 foot pounds. The *total* energy given off by this accumulator in the course of three hours was 3,975.51 × 3 × 60 = 715,591.8 foot pounds; therefore, one cell of 137.28 ampere hours useful capacity, working at the above average current rate and E. M. F., will yield .12047 h. p. for three hours.

In table ii. the same cell gave 44.68 watts, or .06 h. p. for seven hours, which represents 831,600 foot pounds, a gain of 116,008 foot pounds over that in table i.; this again shows the advantage of a low rate of discharge; the loss of energy through the rapid rate of working approaches 14 per cent.

RELATION OF STORED ENERGY TO QUANTITY OF ACTIVE MATERIAL.

The available amount of *energy* is of greater importance than the capacity of a storage battery; the one expresses the actual work done, whereas the other merely gives the current and the time. We have already seen that the available energy of an accumulator varies with the rate of working, consequently the relation between energy and quantity of material must also change according to circumstances. We have on a former occasion ascertained that the total weight of peroxide and spongy lead in the cell (*a*) for locomotive purposes is 11.5 pounds. We have also calculated that this cell, when discharged at the rate of 45.76 amperes, will yield a total energy of 715,591.8 foot pounds; hence in this case each pound weight of active material gave $\frac{715,591.8}{11.5}$ = 62,225 foot pounds. Whilst discharging at the rate of 22.34 amperes the "output" was 831,600 foot pounds, or 72,313 foot pounds per pound weight of active substance; this is equivalent to 2.19 h. p. per minute per pound of material.

INTERMITTENT DISCHARGE.

If we interrupt the process of discharging and allow the plates a moment's rest, then we obtain on rejoining the circuit an E. M. F. and current slightly above that which was observed just before the interruption. By such intermittent discharges it is possible to obtain tolerably regular results even at very high current rates. The gases have time to arrange themselves, whilst the liquid obtains access into the pores of the plates. An accumulator is just like a horse; if you give the horse its regular easy work to do, then he will go along at a constant rate all day long; give him too great a load, then he will gradually lose in speed until he comes almost to a standstill; allow him to "blow" for a quarter of an hour occasionally and he will get along with the great load at a good rate during the regular intervals. But if we take the time as well as the energy into consideration, then we find that the steady easy work will turn out more efficient than the great exertion with intermittent rest. Efficiency, however, does not always mean economy, and there are numerous cases where a small secondary battery worked at a high rate is far more economical than the more efficient larger apparatus working under its normal conditions. The efficiency in *ampere hours*, for instance, yielded during the experiment of table i. was barely 79 per cent., whereas that of table ii. is nearly 90 per cent. But in the one case the energy is diffused in the short space of three hours and in the other in seven hours; and the rate of energy given off in table i. is twice as great for the same weight as in table i.

RESISTANCE OF A SECONDARY BATTERY.

The internal resistance of a storage battery is a variable quantity; it is least when the cell is fully charged, and most when the same is discharged, and it varies with the rise or fall of the specific gravity of the electrolyte. Sulphate is being formed on the lead plates during the discharge, and the same is again dissolved during the process of charging, consequently the strength of the sulphuric acid in a cell will vary continually, and it is possible to measure approximately the quantity of energy stored or withdrawn at any time by the specific gravity of the electrolyte. Results of extensive experiments made by the author upon this point will be discussed hereafter under the subject of sulphating.

The internal resistance of a cell can easily be calculated from the observed current, E. M. F. and external resistance by means of Ohm's law, $C = \frac{E}{R + r}$ where C represents the current in amperes, E the electromotive force in volts, R the known external circuit resistance, and r the internal resistance of the battery.

In table i. we find the rate of discharge at 10 a. m. to be 46.65 amperes with 2.04 volts at the terminals, and an external resistance of .0433 ohms; the internal resistance at this moment is approximately .0004 of an ohm. At 12.45 p. m. the current dropped to 40.66 amperes, the E. M. F. to 1.87 volts, and the internal resistance rose to

$$r = \frac{1.87 - 1.74838}{40.66} = .00299 \text{ of an ohm,}$$

or over seven times the resistance calculated for the commencement of the discharge.

In table ii., again, with a current of 22.56 amperes at 9 a. m., an E. M. F. of 2.04 volts through an external resistance of .089 ohms the internal resistance was nearly .0004 with the cell fully charged. At 4 p. m. when the current dropped to 20.7 amperes and the E. M. F. to 1.9 volts with the same external circuit, the internal resistance rose to .0028 of an ohm, exactly seven times that which was observed at the commencement of the discharge.

The resistance of a battery may be reduced by increasing the strength of the acid, but this cannot be carried beyond a certain limit, and this limit is determined by the minimum density requisite for the formation of a definite amount of sulphate; this internal resistance can also be reduced by placing the plates closely together (here, again, we are guided by a minimum volume of electrolyte); and finally the resistance can be reduced by increasing the surfaces of the plates, and this means enlarging the battery beyond the intended capacity. Therefore we are bound to allow a certain internal resistance, below which it would be difficult to go without sacrificing something else of greater importance, for, after all it must be admitted that the resistance of a well constructed secondary battery is exceedingly low in comparison with the circuit resistances usually connected with it.

EFFICIENCY OF SECONDARY BATTERIES.

M. E. Reynier, in a communication to the Physical Society of Paris, in May, 1881, ascertained the efficiency of storage batteries in the following manner:—Writing E for the E. M. F. of the battery, E_1 the E. M. F. of the charging apparatus, r the resistance of the accumulator, E_{11} the difference of potential at the lamp terminals, R the resistance of the external (lamp) circuit, R_1 the resistance of the charging apparatus, t the time of charge, t_1 the time of discharge, W the work expended by the charging apparatus, and P the useful work applied in the external circuit; then he argues algebraically thus:—

$$W = E_1 \frac{E_1 - E}{R_1 + r} t$$

$$P = \frac{E_{11}^2}{r + R}$$

Digitized by Google

then he assumes that

$$\frac{E_1 - E}{R_1 + r} t = \frac{E_{11}}{r + R} t_1$$

whence

$$t_1 = \frac{\frac{E_1 - E}{R_1 + r} t}{\frac{E_{11}}{r + R}}$$

Substituting for P, we obtain the equation

$$P = \frac{E_1 - E}{R_1 + r},$$

whence he obtains the efficiency

$$f = \frac{P}{W} = \frac{E_{11}}{E_1}.$$

Expressed in words, M. Reynier determines the efficiency by dividing the difference of potential at the lamp terminals by the E. M. F. of the charging dynamo; and he makes the efficiency independent of the resistances as well as of the time and current.

From a numerical example, where $E = 2.15$; $r = .006$; $E_1 = 2.36$; $R_1 = .006$; $E_{11} = 1.93$; and $R = .054$; M. Reynier obtains $f = \frac{1.93}{2.36} = 81.8$ per cent.

The foregoing argument can only be accepted if the charge in ampere hours equals the discharge in ampere hours; such, however, has not as yet been found possible in practice; the time and the current density play as important a part in calculating the *efficiency* of a storage battery as the E. M. F's. The efficiency of a storage battery should be expressed independently of all external influences, such as circuit resistance, resistance of the generator, etc., and it is usual to ascertain it by the expression

$$f = \frac{c \times t \times E}{c_1 \times t_1 \times E_1},$$

where c_1 = the charging current, c = the discharge current, E_1 the charging E. M. F. at the terminals of the battery, E the average E. M. F. of the cells when discharging with an average current, c; t_1 the time (in hours) of charging, and t = the time (in hours) of the discharge.

Examples: The current used for charging the cells (a) was 29 amperes, with an E. M. F. of 2.4 volts per cell; the time occupied in charging was six hours for both experiments i. and ii. The discharge, however, of table i. yielded an average current of 45.76 amperes for three hours, with an average E. M. F. of 1.964 volts, the efficiency, therefore, for this

$$= f = \frac{45.76 \times 3 \times 1.964}{29 \times 6 \times 2.4} = .645,$$

or 64.5 per cent.

The results of the test in table ii. were much higher; there we have with 22.34 amperes and two volts a steady discharge for seven hours, giving an efficiency of

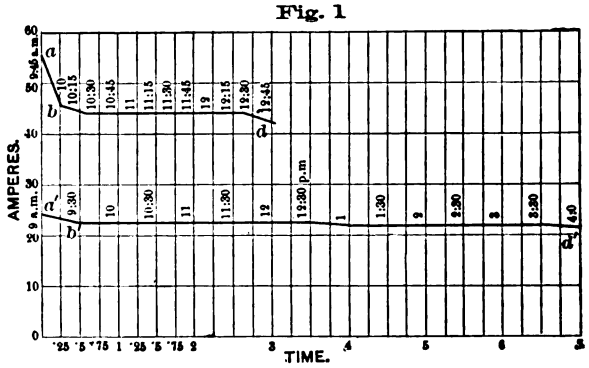
$$\frac{22.34 \times 7 \times 2}{29 \times 6 \times 2.4} = 74.9 \text{ per cent.}$$

Considering that the charging of these cells was effected at the comparatively high rate of 29 amperes, we must admit that an efficiency of 74.9 per cent. is exceedingly favorable; at a still lower rate of charging and discharging, and with more frequent readings, it is possible to obtain even higher efficiencies; but laboratory tests should not be taken as a basis of calculations intended for commercial purposes. We have already stated that a commercial efficiency of at least 70 per cent. may be relied upon in all cases where storage batteries are used under normal working conditions, and this we propose to bear in mind at all times when prime costs, consumption of fuel, maintenance, depreciation, and kindred questions come to be studied in detail. Until recently it has been a matter of opinion with engineers as to the expense of an installation containing storage batteries. Manufacturers and others interested in the exploitation were apt to exaggerate the durability, efficiency, and other virtues of accumulators. Prejudiced opponents, on the other hand, denounced the storage battery not only as an expensive, almost useless, adjunct to an installation, but they predicted with emphasis that the storage battery could never become a commercially successful article. Among these prophets was Edison, the wizard of Menlo Park; perhaps he, like many others, has been converted by this time. We do not intend to convey the impression that the secondary batteries of the present day are perfection and incapable of further improvements; far from it, but we can now point to remarkable and economical results attained with storage batteries; results which compel us to keep our attention constantly alive, results which encourage us to renewed efforts in the direction of further improvement. Many have entered the field of competition, but astonishingly few have kept to it. It is all the more praiseworthy for the few survivors to have stuck to their difficult task; they find their perseverance rewarded. What we want now is a greater number of energetic men in the field, a healthy, honest competition, improvements which will lower manufacturing costs, more tools, more men, more factories to supply the ever increasing demand. We want to push new inventions which do not infringe existing rights and these rights can easily be ascertained with precision. There is no need of treading on anybody's toes, the margin is wider than the uninitiated imagine; there is no chance of a monopoly excepting for those who are powerful and clever enough to produce the cheapest, most durable, and most efficient storage battery on lines different from their forerunners. The whole world is in need of accumulators, and there is room for plenty, if only a sufficient force devote itself with intelligence to one of the most interesting, and, at the same time, one of the most promising of modern industries.

GRAPHIC REPRESENTATIONS.

In order to appreciate fully the internal working of a secondary battery, it is best to construct curves; there we can see at a glance the variations which take place in the course of an experiment. Such curves for secondary batteries are as useful and as instructive as the indicator diagrams of a steam engine. Figures 1, 2 and 3 are taken

Fig. 1



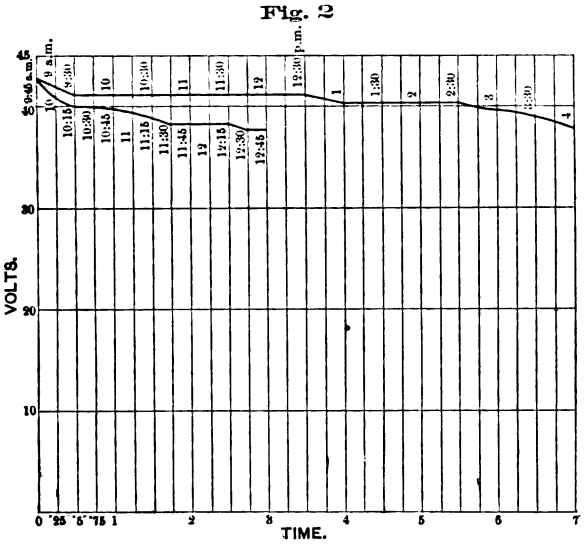
from table i. and ii. (page 174). For the abscissæ in each we take the time in hours, and for the ordinates we plot in figure 1, current in amperes, in figure 2, E. M. F. in volts, and in figure 3, energy in watts. On each diagram there are two curves, one showing the discharge at a high rate (table i.), and the other at the normal working rate (table ii.) of one and the same cell.

Digitized by Google

FALL OF E. M. F. AND CURRENT.

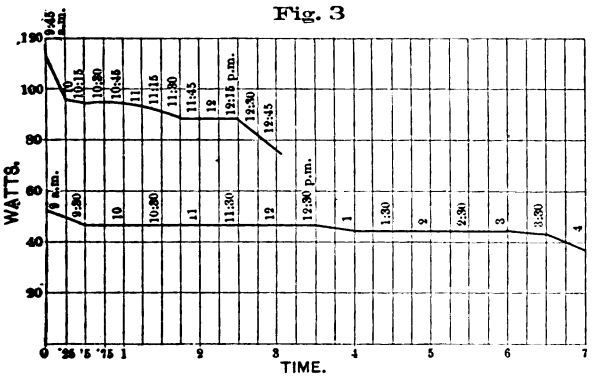
Let us examine the whole process by means of the curves thus plotted. Looking at figure 2, we observe a rapid fall during the first few minutes between the points *a*, *b*, on the one and a^1, b^1, on the other. This drop in the current density was partly due to an increase in the external resistance which was composed of iron tape, and which resistance rose slightly as the metal got heated, but a very similar and sudden decrease of current always takes place in a fully charged lead accumulator, whose initial E. M. F. is

Fig. 2



generally between 2.15 and 2.25 volts per cell, and which high E. M. F. is due to the gases suspended on the surfaces of the plates; we have, in fact, at the first instant a gas battery, the spare oxygen or ozone of which is speedily consumed. Another cause of this diminished intensity, according to Dr. Lodge, lies in the fact that as the surface hydrogen disappears, a scum of sulphate is formed on the negative plate; this film of sulphate increases the internal resistance of a cell more than it diminishes the E. M. F., but it considerably reduces the strength of a powerful current. The greater the current rate, when the

Fig. 3



cell is being discharged, the more will be the resistance offered by this scum, and this is the main reason why a cell refuses to give very strong, and at the same time, constant currents for prolonged periods. "On allowing the cell to stand," says Dr. Lodge, "the scum clears off, and the original power is to a great extent restored. And there is this to be noticed about the scum, that the faster it is formed the faster it clears off. If it is formed very rapidly by a very powerful current, the cell need not stand long to recover itself.

The clearing away of this insulating film is supposed to be due to "the local action between the dehydrogenized lead in the deeper layers of the coating and the hydrogenized lead of the surface; and if this is so, there must come a time when the film will refuse to clear off, and a permanent increase in the internal resistance will set in, increasing as the action penetrates deeper and deeper into the negative coat, until the still metallic lead can only be reached by penetrating through a surface layer of non-conducting matter, consisting mainly of sulphate, but also," Dr. Lodge thinks, "of the lower oxides of lead."

Prof. Herschel made experiments some four or five years ago with a clean lead plate, and a plate coated with peroxide, both being immersed in diluted sulphuric acid; he discovered that a non-conducting film of sulphate was formed on the clean plate the instant it was used to produce a current, which effectually screened the liquid from the metal, and thereby caused an increase in the internal resistance. This scum never forms when the negative plate is standing idle in the acid, it can only form when the circuit is completed. Recharging the cell removes the scum from the negative lead strip, not apparently by reducing it, but by making it peel off. If, instead of using a clean homogeneous lead plate, we employ spongy lead, exposing a very large surface, then this film takes a much longer time to form. The constancy of the current depends upon the amount of hydrogen occluded, consequently the *rate* of discharge must be in proportion to the total available surface. The diagrams before us illustrate this most forcibly; assuming that the rapid fall during the first 15 minutes is partly due to temporary causes indicated at the beginning of this paragraph, we still find that in the endeavor of working the cell at a very high rate, the current is reduced from 46.65 to 40.66 amperes

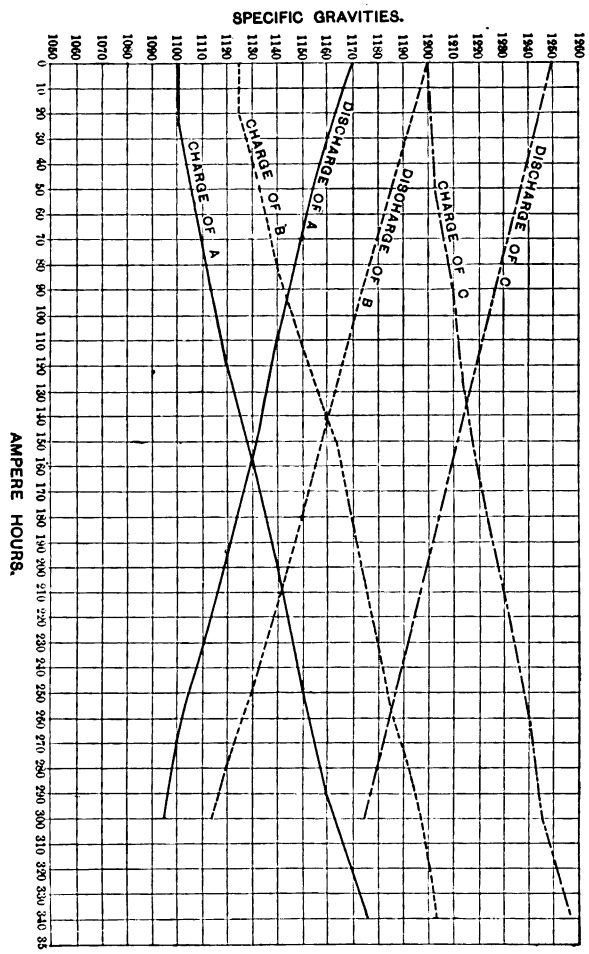


Fig. 4

in the course of 2.75 hours, whereas at a reasonable rate of discharge the difference is only 1.86 amperes during 6.75 hours. We can only obtain a large working surface within a small space, by using finely divided lead, oxides of

Digitized by Google

lead reduced to spongy lead for the negative plate; it is furthermore important that the layer of spongy lead be of a moderate thickness, because full activity will only take place to a certain depth, since the acid can either not penetrate sufficiently into the porous mass, or it gets speedily exhausted within as it combines with the lead, and clogging occurs beneath through the non-conducting products thus created. In order to facilitate diffusion with the main body of the liquid, the plates must be comparatively thin; in fact, the thinner they are the greater is the activity, and the more constant the discharge, always provided that the *volume* of porous material bears a certain relationship to the total capacity of an accumulator.

SULPHATING.

The formation of sulphate of lead, on lead plates immersed in sulphuric acid, is a natural consequence. Sulphate is a necessity; without it the charge could not be retained for a long time, and, above all, it prevents local action between the metal and its oxides, but a superabundance of this compound of lead is detrimental to the life and proper function of a secondary battery. Whilst charging, the lead sulphate on the plates is decomposed and re-formation of sulphuric acid takes place, so that ultimately the strength of the solution is fully restored. On discharging again, lead sulphate is produced on both the positive and negative plates, and thereby the strength or specific gravity of the acid becomes diminished.

STRENGTH OF ACID.

Concentrated sulphuric acid is a bad conductor, so is pure water, but a mixture of the two furnishes a good conducting medium. The best density of the mixture depends upon various circumstances; if the acid is too strong there is a tendency of an excess of sulphate being formed on the plates, causing them to expand and finally buckle when discharging; if the solution is too weak, then there is the danger of almost pure water being left at the end of the discharge, and, consequently, great internal resistance. When a cell is newly made up with "formed" plates and the acid is put in, the specific gravity will drop immediately, indicating the formation of sulphate; on charging the cell the strength of the acid will gradually rise again. Tables iii. and iv. were prepared with a view of illustrating this phenomenon. There were three cells used, A, B and C, of equal size and capacity; cell A was filled with acid of 1,100° (water taken at 1,000), B 1,125, and cell C with acid of 1,200. Immediately after pouring the liquid into the boxes circuit was made with the charging apparatus, but some 20 amperes for one hour were expended before any change in the density of the liquid took place;

TABLE III.—CHARGING CELLS.

Ampere hours.	Densities of acid.		
	A.	B.	C.
0	1100	1125	1200
20	1100	1125	1200
50	1105	1133	1203
100	1115	1143	1211
150	1127	1164	1218
200	1139	1174	1229

300	1162	1200	1245
340	1175	1208	1256

there was even a tendency of the specific gravity falling in spite of the charging operation; thus there must have been a kind of equilibrium between two opposing forms of energy; one struggling to produce sulphate and the other struggling to reduce it.

After this expenditure of 20 amperes of current at some 2.38 volts E. M. F. per cell, the specific gravity began to rise almost in proportion to the amount of charge put into the cells. Diagram, figure 4, will show the effect more strikingly than the tables; the charge in ampere hours is taken for the abscissæ and the specific gravities for the ordinates. The acid of A which was at the start, 1,100, rose to 1,175; that of B rose from 1,125 to 1,208 and the density of the acid in C went up from 1,200 to 1,250, all with a charge of 340 ampere hours. The cells were left standing over night; next morning on observing the hydrometer (or acidometer) the densities stood at 1,170, 1,200 and ,1250 respectively for A, B and C, giving a reduction of 5, 8 and 6 degrees in the liquids. This discrepancy may be attributed to three causes: firstly to

TABLE IV.—DISCHARGING CELLS.

a slight formation of sulphate; secondly to surface leakage; thirdly, and, perhaps, *mainly*, to strata of different specific gravities in each cell. The liquid in the lower portion of a newly charged cell is generally slightly more acid than that near the surface; the hydrometer bulb dipped into the lower part of the vessel and, therefore, did not indicate the *average* density, if the assumed strata existed. Theoretically the acid curves of figure 4 should all be straight lines—they are so approximately only, and the irregularities are no doubt due to the last-mentioned causes. Diffusion of the liquids can be assisted by stirring, but it will be observed that in doing so large gas bubbles float up immediately which may mean some loss in the capacity; towards the end of the charge, if the same is carried to completion and the liquid is allowed to "boil," by a little over-charging, the acid gets stirred up automatically, A, B and C were not overcharged.

(*To be continued.*)

ELECTRICAL TRANSMISSION OF POWER BY BROWN'S DYNAMOS.[1]

WHILST steady progress is being made in almost every branch of electricity, the theory developed and the instruments perfected, the most interesting question, the electrical transmission of power, which first roused the enthusiasm of the scientific and unscientific, seems to remain a *pium desiderium*. The Niagara Falls still waste their energy instead of enlightening and benefiting the whole State of New York and the adjoining districts of Canada; and the waves continue to gnaw at the British Isles without giving any return by supplying the lighthouses with the necessary light currents. A few isolated cases are known where electricity affords the satisfactory means of utilizing at a distance the power which is cheap but useless at one particular spot; but we hear nothing of permanent installations on a large scale. At the Vienna exhibition of 1873, a gas motor was made to drive an electric machine whose current was sent to another electric machine which actuated a little centrifugal pump; that was an experiment. Such experiments were repeated at the exhibitions at Philadelphia, Paris, London, Munich, and again at Vienna, everywhere exciting the most lively interest. At Munich, M. Marcel Deprez made a very decided and promising step forward; his continued tests between Paris and Creil, a

1. From *Engineering*, London, March 11.

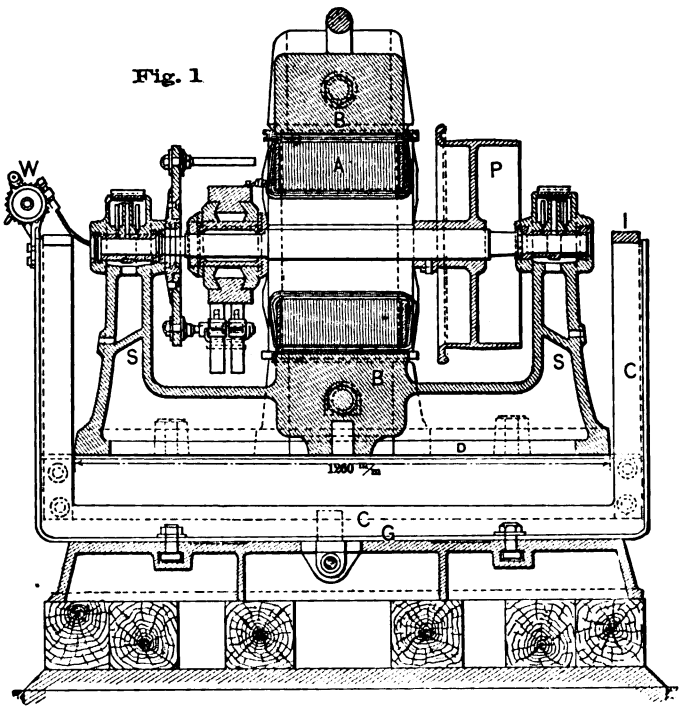
distance of 35 miles, followed ; but a long time passed before any definite results were published, and it required the munificence of Baron Rothschild to render the tests possible. The uncertainty about the results had shaken confidence, and when it became known finally that the commercial efficiency had not risen above 45 per cent., many a practical engineer returned to his old opinion that, after all, the transport of coal was cheaper than the transport of power in any form.

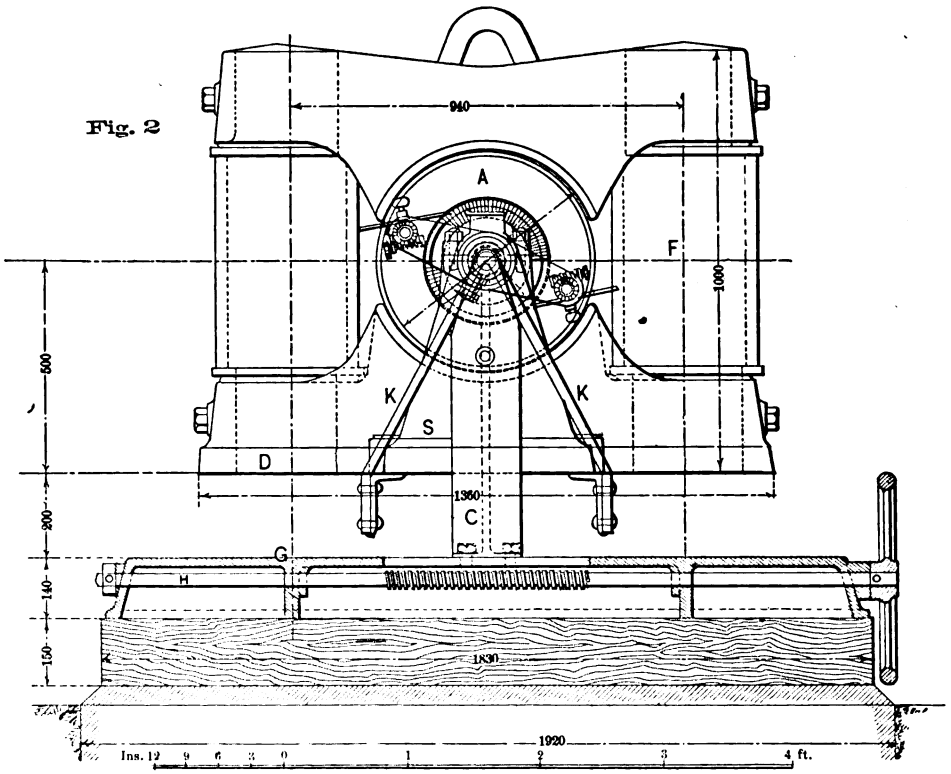
Under these circumstances all further experience is most welcome. We are to-day enabled, through the courtesy of Mr. C. E. L. Brown, of the Tool and Engine Works at Oerlikon, near Zurich, to place before our readers the results of some tests on the electrical transmission of power, made with Mr. Brown's new dynamos and motors. The tests were conducted by the maker in conjunction with independent and competent experts, Professors Amsler-Laffon, Gysel, Veith and Weber, and Messrs. Keller, Lang, Meier, Naville, Waldner, and Zschokke ; the report was compiled by Prof. Amsler-Laffon. The machines were constructed for the transmission of a water power of about 50 horse from Kriegstetten over a distance of 8 kilometers (five miles) to the works of Mr. Mueller-Kaiber at Solothurn, in Switzerland. The tests were made in the works of Mr. Brown, on conditions as nearly as possible equal to those to be fulfilled later on ; their object was a practical one; to answer the questions : What power must be supplied to the primary machines, so that the secondary machines can do a certain work ? What relations exist between the speed of the primary and of the secondary machines ? How does the speed vary with varying work ? Electrical instruments were used only so far as electrical magnitudes were directly concerned ; the power measurements were taken mechanically. We will conclude these introductory remarks by adding that a commercial efficiency of over 70 per cent. was obtained.

Fig. 1



The general design of the dynamos will be understood from diagrams ; figure 1, a longitudinal section, figure 2, an end elevation, and figure 3, the plan, showing the construction. Two vertical pillars, F, of wrought-iron form the field magnets ; they are united by cast-iron blocks, B, acting as pole pieces. The lower block B, the bed-plate D, and the supports S, for the armature A, are cast in one piece. The armature of the motor is a modified Pacinotti-Gramme ring. We are not in a position to give a detailed description of the peculiarities of this armature; but it appears clear that the remarkable efficiency of Mr. Brown's dynamo must be ascribed to the ingenious though simple alterations which he has made in the armature and its relative position to the field magnets. The shaft bears the armature on the one end, and the pulley P on the other, that is, within the bearings. One of the first dynamos embodying these improvements gave at a speed of 1,000 revolutions per minute a difference of potential at the terminals of 65 volts and a current of 160 amperes ; the armature wire weighed 12 kilogrammes (26 lb.) with a resistance of 0.008 ohm ; the field magnet coils weighed 33 kg. (73 lb.), and had a resistance of 25 ohms. The newer dynamos for the Solothurn installation are of a larger type, and give about 1,200 volts each, with the normal speed of 700 revolutions per minute. Their principal dimensions are : Total length, 4 ft. 1 in.; width, 4 ft. 5 in.; height, 3 ft. 3 in.; diameter of armature, 20 in.; length of armature, 12 in.; and diameter of pulley, 20 in.; width, 7 in.

Fig. 2

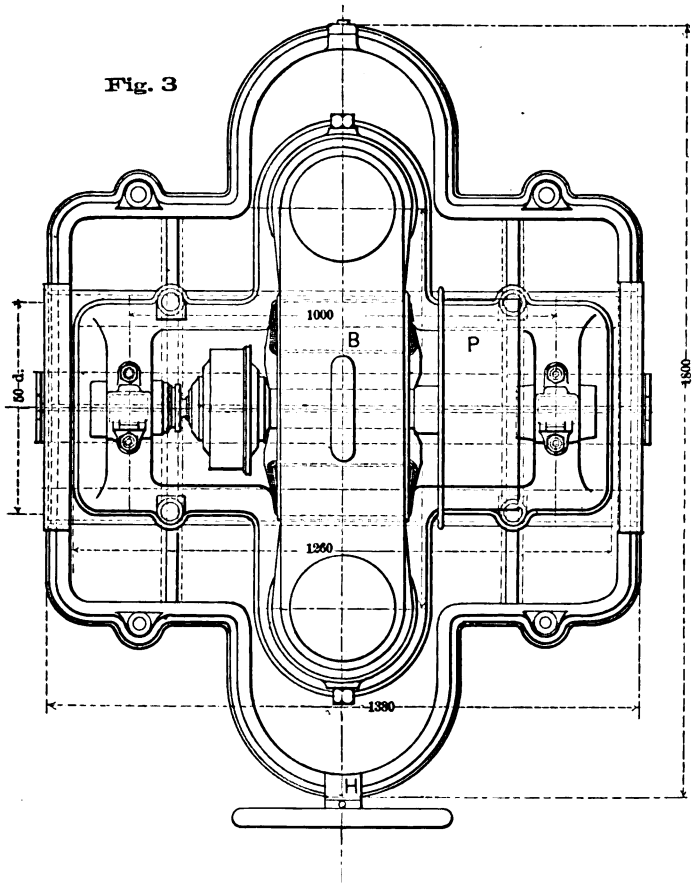


As reliability is the first requirement, Mr. Brown decided to use four machines, two generators and two motors, so that in cases of emergency one pair alone could take the main part of the work ; the water-power to be transmitted varies between 30 and 50 h. p. A speed of 700 revolutions was selected, both as being economical and not too high ; a lower speed would have required heavier and more expensive dynamos. The three lead system has been adopted, all three wires being naked pure copper wires of six millimeters ($\frac{1}{4}$ in. in diameter) suspended on poles about 120

Digitized by Google

feet distant from one another with fluid insulators; the river Aare is crossed by one span of 380 feet length of a silicium bronze wire, having about the same thickness and equal conductivity as the copper wire, but possessing at least double the tensile strength. With the two generators in series an electromotive force of 2,500 volts is obtained. The three wire system offers the advantage that should one of the motors stop, the other would never receive more than one-half of the total tension; an arrangement has further been made by means of which one of the outer wires can be connected parallel with the central wire, in case one of the generators should have to work alone; thus the loss in the conductors would not be doubled, but increased by one-half only. The primary station comprises besides the two generators two automatic shunts short circuiting the field magnets in case the currents should become dangerously strong—two ampere meters—and further, three lightning conductors with lightning plates of an original kind for the protection of the dynamos against

Fig. 3



lightning. The secondary station is equally protected; it contains further two fluid cut outs permitting of stopping the two motors suddenly without endangering the insulation.

The contract required a constant speed independent of the work to be done as a main condition. Constant speed may be secured mechanically or electrically. Electrically this regulation may be effected by various methods, three of which command particular consideration. The first method uses a primary dynamo (generator) of the compound type, and a simple shunt motor for the secondary station; this arrangement recommends itself for medium tension currents. The second method has compound wound machines for both the primary and the secondary stations; the object of the series wire being in the first case to supply a higher tension for a greater load, and in the second case to weaken the magnetic field of the motor proportionally; this arrangement offers advantages when one generator has to feed several motors. The third method takes series dynamos for both stations, and as it is particularly adapted for high tensions, and when one primary station has to supply one secondary, it was selected here as we mentioned already; it further admits of easy starting, even with a full load. With properly designed and constructed dynamos this arrangement ought to turn the motors with a constant speed, provided that the generator rotates at a uniform rate. Mr. Brown finds that when varying the brake power applied up to 20 per cent. the speed of the motor did not vary by more than three per cent. These slight variations might further be reduced if it should become necessary.

We come now to the test at the Oerlikon works, carried out under the actual conditions under which the dynamos will have to work, the line wire of 9.5 ohms resistance being replaced by an iron resistance of 10 ohms. This iron wire was shortened in proportion to its becoming heated through the current whose strength was controlled by means of a voltameter; thus the resistance was kept constant. Being aware of the diffidence with which the practical engineer regards electrical power tests, in which he has to trust electrical instruments of whose reliability he cannot convince himself by experiments of his own, Mr. Brown decided in favor of mechanical power tests. All the four dynamo machines were suspended in cradles, C, bolted to a baseplate, G, which was provided with a screw spindle, H, for the adjustment of the belts. The vertical limbs of the cradles end in knife edges, I; and on these the whole dynamos rested, being held by an iron strap, K, which strap was firmly bolted to the dynamo bedplate, D. The edges, J, were placed exactly in the prolongation of the armature shafts. Pointers of 6 ft. length were attached to the field magnets; and the power applied, or required, calculated from the deflections from the vertical line which the generators suffered under the pull of the belts from the steam engines, and the motors under the influence of the currents transmitted from the generators. The speeds were indicated on a counter connected with the armature spindles by a flexible shafting and a worm gearing, W. This method of estimation necessitated preliminary trials to ascertain directly by weights applied to the pulley P, the power corresponding to the different positions of the pointer. For this purpose the armature was rigidly fastened to the field magnets during these trials; thus a power scale was obtained, indicating in kilogrammes the weights which acting on a lever arm of 0.25 metre (9.8 in.) —the common radius of all the pulleys, P—produced the respective deflections.

The total resistance of the four dynamos connected in series—that is, the two generators in series connected in series with the two motors, also in series—amounted to 13.44 ohms; adding to this 10 ohms for line resistance, we get the total resistance of the system equal to 23.44 ohms. The belts having been put on the primary dynamos the motors were coupled to a light machine whose circuit resistance was increased by adding arc lamps. When the generators made about 100 revolutions per minute, the motor armatures began to spin; the deflections of the pointers soon become stationary. All corresponding observations were taken within the space of one minute.

The tests were made on five days in November, 1886; the principal tests, which we summarize, on November 22d and 29th. Table i. gives first the results of the tests of November 29th. The columns P_1 and P_2 refer to two primary machines, S_1 and S_2 to the secondary machines; those marked T state the speeds, Z the deflections of the generators; the same letters with dashes apply to the motors; column E gives the current strength in amperes. The deflections under Z are given in kilogrammes, as has already been explained. The speed counter for P_1 failed after 14 observations had been taken. The figures in parentheses were only estimated. The lower part of table i. relates to the tests of November 22d; two further tests of November 30th are subjoined. Table ii. refers to the

Digitized by Google

same tests, giving the corrected values after elimination of possible errors. The suspension of the dynamos proved very delicate and satisfactory. There was, however, magnetic attraction between the dynamos and the ground-plate G, the distance from the bed-plate D to G being only about ½ ft. It was ascertained that this magnetic attraction would lead to too low readings when the pointer was near zero, but would be without influence when the pointer was near 40; and would cause too high readings after that. This was determined by passing electric currents through the field magnets and forcing the pointer gradually over the scale by loading the machine, regulating the currents to the strength which the tests (table i.) had shown to correspond to the respective position of the pointer. The error is very slight, and attains practical importance only for the readings above 80, when reductions have been made, ½ kg. for 80 kg. to 90 kg., 1 kg. for 90 kg. to 100 kg., 2 kg. for 100 kg. to 110 kg., 3 kg. for 110 kg. to 115 kg., and 4 kg. for 115 kg. to 120 kg. The belts might further tend to shift the cups of the strap K, slightly on the knife edges J, and since the pointer scale was determined when the belts were off, these errors would only appear whilst the dynamos were at work, and not during the preliminary trials. This error, again, could only be insignificant, as the radius of curvature at the cups was very small. Yet this shifting had actually occurred in the case of the generator P_2, for its pointer did not go back to zero when the machines were stopped, but stood at 2½ kg. Similarly, the motor S_1 had been shifted a little, of course in the opposite sense, its pointer pointing to 1 kg.

The whole method has carefully been analyzed by Prof. Amsler-Laffon. The position of the pointer will depend upon the electrical reaction between the armature and the field magnets; the friction in the bearings, and the resistance which the moving armature and pulleys encounter from the air. We have further unavoidable losses of power within the dynamos, and the mechanical defects which would accompany any mode of suspension. As we have just mentioned, the belts might be expected to pull the dynamos slightly out of their central line, shifting them horizontally; a slight deviation from the central axis might also occur in the vertical plane; and lastly, we have the magnetic attraction between the dynamos and the ground plate G, already alluded to. Prof. Amsler convinced himself that these sources of error could not materially affect the results. That this opinion is justified, he proves by determining the efficiencies first, directly from the figures observed, by dividing the power A_1 imparted to the generators into the power A_2 yielded by the motors, this calculation giving the column $\frac{A_2}{A_1}$, or efficiency in per cent; and secondly, by subtracting from the powers—absorbed or reproduced respectively—the powers corresponding to the minimum loads, and thereby eliminating those possible errors which cannot be controlled experimentally, but which would be the same for higher and smaller loads. A_2 and A_1 represent the powers received or expended in each particular case, A_2^0 and A_1^0 the same for minimum loads derived from the means of experiments No. 1 and No. 2, table ii., thus $A_2^0 = 3.25$; $A_1^0 = 4.48$; if we then form the quotient of the differences $\frac{A_2 - A_2^0}{A_1 - A_1^0} = Q$, we arrive at the commercial efficiencies by a method independent from the sources of error which influenced the figures in column $\frac{A_2}{A_1}$. It will be seen that there is a most satisfactory agreement in the commercial efficiencies as determined by these two methods; those under Q are, of course, the more reliable figures.

Prof. Amsler-Laffon adds a few recommendatory remarks to his report. The Brown dynamos are distinguished by a simple, solid, and judicious construction; the brushes are easily accessible, showed very little sparking, and did not require any adjustment during the tests when more and more lamps were added; there would thus be very little wear to both brushes and collectors. The field magnets became only slightly warmer during a run of several hours. The speed—700 revolutions per minute

							Mean	76.9	

Observations Nos. 9, 10, 14, 15, 16, where power transmitted exceeded 30 h.p., yield mean efficiency 73.9 per cent.

—Prof. Amsler regards as rather high. Since, however, the speed of the motors remained practically constant during the trials—increasing a little with augmented resistance in the exterior circuit—and deviated little from the speed of the generator, provided the latter was driven at a uniform rate, it appears hardly advisable to try to reduce the speed

Digitized by Google

for the sake of questionable improvements. Prof. Amsler acknowledges further the excellent provision by means of automatic short circuiting devices against too strong currents; and finally dwells upon the remarkably high efficiency realized, which is scarcely likely to be surpassed.

We must bear in mind that the percentages indicate commercial efficiencies, as they represent the ratio of power yielded to power expended, both measured mechanically. The performances of electric machines have been calculated in so many different manners, that it may not be superfluous to set this point clear. The tests of November 29, yielded a mean efficiency of over 70 per cent.; Mr. Brown's previous tests of November 29, gave a mean of 76.9 per cent. This difference requires an explanation; and the reason is pretty apparent. On November 22, both primary generators worked with approximately equal power, hence the differential current in the central wire of the three wire connection was almost zero, and the loss of energy consequently a minimum. On November 29, however, these powers differed very considerably, in some cases by even more than 100 per cent.; a glance at the columns z_1 and z_2 of table i. will establish this; table ii. gives the means, and therefore does not permit any conclusions as to the different working conditions. Heavier currents could not but result under these circumstances; hence the lower efficiency. We have above referred to M. Marcel Deprez's experiments and their maximum mechanical yield of 44.8 per cent. Of course, M. Deprez's line was much longer and had a resistance ten times as great, nearly 100 ohms. As his current was 9.8 amperes, his line absorbed almost 13 h. p. out of the 86 indicated by the dynamometer at the generator; M. Deprez had only one generator, a powerful Gramme dynamo giving a current of 6,000 volts. It will be interesting to mention for comparison the experiments on the electrical transmission of power by M. Hippolyte Fontaine, the results of which were, like those of M. Deprez, presented to the Paris Académie and published in the *Comptes Rendus*. The data of the two tests were almost the same, M. Fontaine also transmitting his currents of 6,000 volts and 9.34 amperes over a line of 100 ohms resistance; but M. Fontaine's experiments resemble more those of Mr. Brown in one respect, as M. Fontaine had four dynamos in series as generators and three in series as motors, similar to the two generators in series and the two motors in series of Mr. Brown. In M. Fontaine's line almost 12 h. p. were lost out of 96 h. p. supplied to the generator; his industrial yield was 52 per cent. If we make the same calculation with regard to the power absorbed by the line in Mr. Brown's tests, we find (in No. 14) with a current of 15 amperes and a line of 10 ohms resistance, a loss of about 3 h. p. against 62 h. p. measured at the generators. But it would, of course, be incorrect to deduct 13 per cent., which were expended in overcoming the resistance of M. Fontaine's line, for the Oerlikon case, and to calculate thus an efficiency of over 64 per cent. for the Brown dynamo when working over a line of M. Fontaine's length, since the whole conditions would be altered, and since the dynamos were not constructed for a line of 100 ohms resistance. But the comparison speaks very favorably for Mr. Brown's dynamos, particularly if we consider that the tests, when the power transmitted exceeded 30 h. p., that is, when they corresponded to the actual conditions for which the plant was designed—tests Nos. 9, 10, 14, 16—demonstrated a mean efficiency of 73.9 per cent. These are the experiments which were alluded to during the recent discussion of Mr. Sturgeon's paper before the Liverpool Engineering Society.

EQUIVALENTS OF UNITS OF MEASUREMENT.

CARL HERING.

The numbers in these tables have been calculated from the fundamental standard equivalent of the meter in inches, and the gram in grains, as given in the table. Also from the value of the avoirdupois and troy (apothecary's) pound in grains, the gallon in cubic inches, atmospheric pressure in millimeters, and specific gravity of mercury, all, as given in the tables. The values for the weights and volumes of water are based on the metric system. The vulgar fractions are the simplest fractions, that is, consisting of the fewest digits, which have, within a few per cent., the same value as the more accurate decimal fraction. Most of the vulgar fractions are within two per cent. of the correct value, a few are slightly above two per cent. In almost all cases the reciprocals of values are given, thus enabling all calculations to be made by multiplication instead of division. All the figures have been carefully checked by two independent methods, and it is believed that there are no errors.

DUPLEX TELEPHONY.[1]

BY DR. A. M. ROSENBRUGH.

In this paper I desire to call the attention of the members of the Institute to some recent advances that have been made in the direction of duplexing telephone lines. It is now ten years since the telephone was introduced, but it is only quite recently that attention has been directed to duplex telephony. Duplex telephony seems to be adapted to long-distance telephony only. In long-distance telephony the best results are obtained when two wires are used, one wire being used as a return wire,—the two wires forming what is called a metallic circuit. The wires used for this purpose require to be first-class conductors. They are now made of copper. This necessarily very much increases the cost of long-distance telephone lines, firstly because copper wire is expensive and secondly because two wires instead of one are used.

Hence any means or device that will increase the working capacity of telephone trunk lines will proportionately decrease the cost of long-distance communication by telephone.

When I took up this question a little over two years ago, my object was to use the metallic circuit or double wire trunk line system connecting two telephone exchanges so that either two telephone subscribers, or a telephone subscriber and a central office operator at each end of the metallic circuit could communicate simultaneously without interference. In order to accomplish this I found that there were two problems to solve, firstly, how to render the central office receiving telephones neutral to the subscribers' transmitters, and secondly, how to render the

1. Read before the Canadian Institute, January 8th, 1887.

Digitized by Google

subscribers' receivers neutral or irresponsive to the central office transmitters.

The solution of the first problem was not attended with any great difficulty. The plan adopted was as follows, namely: At each central office and at each end of the metallic circuit a subscriber's line was attached. Instead of using the ordinary telephone receiver with a single coil, a telephone with a double coil was used and instead of inserting said coil in a single branch of the metallic circuit, one coil was inserted in one branch and the other coil in the other branch of the metallic circuit and the connections were made so that electrical currents traversing one coil would be neutralized by the electrical currents traversing the other coil. Speaking technically, the coils were connected differentially. The electrical currents generated by the subscribers' transmitters passed through the two coils in opposite directions and consequently neutralized each other. Hence while two subscribers, one at each end of the metallic circuit, were using the line nothing would be heard in the central office telephones.

The first problem having been solved I was encouraged to attempt the solution of the second, namely, how to render the subscribers' telephones neutral to the central office transmitters. This was found to be a difficult problem. It was obvious that if the transmitters were placed in either branch of the metallic circuit, the electrical currents generated by said transmitters would divide at the junction of the subscribers' lines and a portion of said currents would escape to ground through the subscribers' telephones. Without stopping to enumerate the different expedients resorted to, I finally saw that the only solution to the problem was to arrange the central office transmitters so that both branches of the metallic circuit would be charged equally, simultaneously, and in opposite directions. By charging one wire positively and the other negatively at the same time, I saw that the electrical equilibrium between the two wires could be disturbed without affecting the equilibrium of the subscribers' lines. Fortunately after many and various experiments, the means for accomplishing this were discovered, and the problem was finally solved.

I also discovered that this can be accomplished in several ways. I will call your attention to but two of these. The first of these methods is to use a transmitter with two induction coils, the primary coils being connected either in series or in multiple arc, and the secondary coils being connected in circuit, the one in one branch of the metallic circuit and the other in the other branch of the metallic circuit. In the second method repeating coils are used with one coil in each branch of the metallic circuit, said coils being connected with each other and also with an independent telephone circuit.

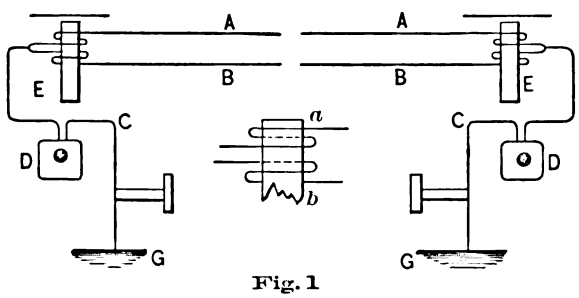

Fig. 1

In figure 1 A. A and B. B. are two branches of a metallic circuit, and C. C'. are two subscribers' lines attached thereto. D. and D', subscribers' transmitters, and E. E. are receiving telephones at two central offices at each end of the metallic circuit respectively. The telephones E. E. have two coils, *a* and *b*, the former connected with wire A. and the latter with wire B. These coils are connected differentially, and the telephones are neutral to the subscribers' transmitters.

In the first method the operation is as follows: The voice impulse vibrates the diaphragm of the transmitter, this varies the strength of the local battery circuit traversing the primary coils of the two induction coils, this generates secondary currents in the two secondary coils, and this in turn generates electrical currents in the two branches of the metallic circuit, and if the two coils are properly balanced, electrical impulses are generated in each branch of the metallic circuit equally and simultaneously, and if the connections are properly made, these electrical impulses traverse the metallic circuit in opposite directions, the currents generated in one coil being reinforced by the currents generated in the other coil.[1] I might mention here, in passing, that the converse is also true, namely, if the connection of one of the coils be reversed, the currents generated by one coil will be opposed by those of the other, and no current will traverse the metallic circuit, the currents will meet, however, at the subscribers' lines, and, being reinforced, will proceed to "ground" through the subscribers' telephones. Advantage may be taken of this fact and two sets of transmitters may be used at the central office or at any point in the metallic circuit, and they may be connected in such a manner that the subscribers' telephones will be responsive to one and neutral to the other.

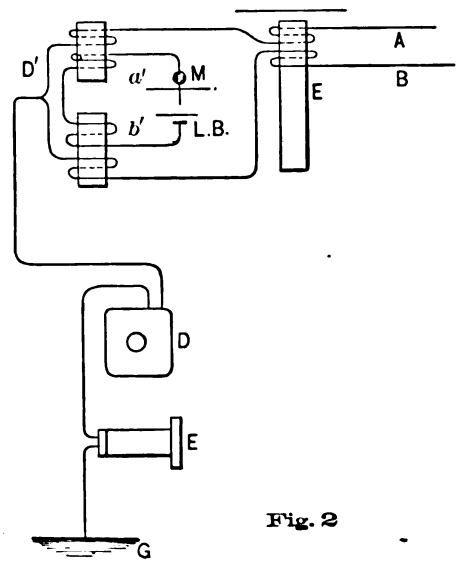

Fig. 2

In figure 2 A. and B. are the two branches of a metallic circuit at one end of a telephone trunk line. C. is a subscribers' line, and E. a receiving telephone in said subscribers' line. D'. is a transmitter with two induction coils at the central office. The secondary coil of coil *a'* is in circuit with wire A. and the secondary coil of coil *b'* is in circuit with wire B. M. is a microphone, and L. B. the local battery connected with the primary coils of *a'* and *b'*. E. is the differentially wound receiving telephone at the central office.

Preferably, however, I would give the subscriber both a return wire and a ground wire, and, preferably, two installations of telephonic apparatus; one a single installation for ordinary use, and the other an installation of duplex apparatus for long-distance telephoning on the metallic circuit.

When repeating coils are used for charging the two branches of the metallic circuit, said branches are charged indirectly through said repeaters. I am aware that there is nothing new in using repeating coils in telephone circuits, but, so far as I am aware, they have never been used as here described nor with the same object in view, namely, to actuate and to be actuated by both branches of a metallic circuit simultaneously. The advantage of using repeaters, as here indicated, is to enable two subscribers at each end of the metallic circuit to communicate simultaneously without interference, one subscriber using a line

1. Adjustable cores are used in connection with the two induction coils for the purpose of balancing, in case the two branches of the metallic circuit are not perfectly balanced.

Digitized by Google

connecting directly with the metallic circuit, and the other subscriber using a line connecting indirectly by means of the two repeating coils. Hence by a combination of these two methods it will be seen that either two subscribers or one subscriber and a central office operator at each end of a metallic circuit may communicate simultaneously without interference.

One important advantage resulting from this arrangement remains to be named, namely, the subscribers have the advantage of two conductors instead of one. This reduces the resistance of the line one-half, and must necessarily very much improve the working of long-distance telephone lines. This idea may be extended as follows: Two metallic circuits may be connected at each end so as to form a third metallic circuit. This third metallic circuit may contain duplex central office telephonic apparatus and form a connection with a subscriber's line as well. This would give the subscriber the benefit of four conductors. The four trunk lines would be formed into three metallic circuits, and three repeating circuits could be used. In other words, the four wires would admit of four subscribers at each end of the line using the same wires simultaneously.

In August, 1885, I communicated my duplex telephone system to Prof. S. P. Thompson, of the Finsbury Technical Institute, London, England, and, through his advice and kind offices, a patent was taken out in Great Britain. An application was also filed at Washington. I submitted my system to the American Bell Telephone Co. in May last, but I have not learned whether it has as yet been put in practical operation. In the meantime two claimants have made their appearance, namely, one J. J. Curry and one J. A. Barrett, the former an employé of the New England Telephone Co., and the latter an employé of the New York Telegraph and Telephone Co., both under the control of the Bell company. One claims the arrangement of the differentially wound apparatus, and the other the arrangement of the repeating coils.

I will conclude this paper by giving two extracts from the New York *Electrical World* bearing upon the subject. The first appeared July 31st, or about two months after my system was submitted to the Bell Telephone Co. It says:—

The great expense attending the construction of copper lines for long-distance telephony has naturally led those engaged in solving the long-distance problems to seek means for increasing the capacity of the wires. The steps to be taken are analogous to those adopted in the case of the telegraph, where the duplex and quadruplex have greatly increased the value of the lines. It is not hard to believe the report, therefore, that the American Telephone and Telegraph Co., a description of whose lines between New York and Philadelphia we gave lately, is now undertaking experiments with the object of duplexing its wires, and thus practically doubling their capacity and utility. Several methods of duplexing telephone lines have already been proposed and have been the subject of discussion and trial among telephonists, but they have not come into use, in this country at least. The delay has been due probably to a lack of necessary incentive, such as the long-distance service now furnishes. While the difficulties to be overcome in the duplexing of telephone lines are greater than with the telegraph, it is safe to say that satisfactory results will in time be attained. We understand that the work in the present instance is in highly competent hands, and even now gives excellent promise of developments scarcely hoped for.

The second notice appeared October 23d last, and reads as follows:—

The telephone lines connecting New York and Philadelphia, recently erected by the American Telephone and Telegraph Co., of this city, have already been described in our columns. It was evident to all interested that lines running parallel for over 100 miles would suffer from induction if the ordinary "grounds" were employed: hence complete metallic circuits of hard-drawn copper wire were erected, through which the articulation obtained, as we have ourselves tested, leaves nothing to be desired. It becomes manifest, however, that the erection of a double circuit is accompanied by a considerable increase in the cost of construction. Hence it is but natural for the company to seek in some way to increase the capacity of its lines, but still to retain the advantages of the metallic circuit.

The duplexing of these telephonic circuits was, therefore, undertaken by Mr. John A. Barrett, of Brooklyn, who has succeeded in devising a system which, broadly stated, *consists in bringing the metallic or double-wire instruments at the terminal stations into inductive relation, by means of converting or repeating coils, with both sides of the circuit.*

The question of priority of invention will be decided by the United States patent office, and I doubt not due justice will be done in the premises.

DYNAMIC ELECTRICITY.

BY CARL HERING.

(Continued from page 148.)

CHAPTER VII.—FIELD MAGNET FRAMES (CONTINUED).

THE application of the formulæ just given may be illustrated as follows: Suppose the magnets of a dynamo which has been tested, were found to be over-saturated too much, and it is desired to construct a new frame for this machine in which they were not to be over-saturated. By the tests which will be described in a subsequent chapter, find what the magnetism must be for the proper load of the machine when the magnets are over-saturated; call this m. It is not necessary to know the actual number of lines of force but merely a number which is proportional to it, such for instance, as the potential in volts measured on open circuit, with the magnets excited to the required degree of magnetization. Make another test to determine the magnetism in the magnets (or the potential on open circuit) when they are just saturated; call this n, and let the number of ampere turns required in this case be c. From n and the area of cross-section of the core, find, by dividing the former by the latter, what the intensity of magnetization per square inch is, just at saturation. If the number of volts has been used instead of the number of lines of force, the number thus obtained for the intensity, will by itself mean nothing, but it will nevertheless, be proportional to the intensity per square inch, and can be used in the further calculations. This intensity is what may be allowed in the new magnets. Dividing the required magnetism m by this allowable intensity, will give the area of cross-section which the new magnets must have in order not to be over-saturated, the quality of the iron being supposed to be the same. From this new area find the diameter, and call it D_1, the old diameter being indicated by D. It then remains to find what the new ampere turns must be in order to develop this intensity. From the formula for the value of I it is evident that if the intensities in two cases are the same the ratios of the ampere turns (c) to the diameter will be the same in the two cases, that is,

$$\frac{c}{D} = \frac{c_1}{D_1}$$

in which c_1 represents the ampere turns required for the new magnets. As the ampere turns c of the old magnets when just saturated, and the old and new diameters D and D_1 are known, the value of the new ampere turns c_1 is readily determined; it will be

$$c_1 = \frac{c}{D} D_1.$$

Owing to some small errors which are involved, these calculations will not be exact, but they will serve very well as a guide.

From this new number of ampere turns and from the dimensions of the old magnets, it can readily be calculated whether the new magnets must be made longer, or whether they may be still shorter. To illustrate this, suppose the old magnets showed no signs of heating when they were being run just at saturation, developing the magnetism which was indicated by n. This would show either that more electrical energy may be used for the magnet coils (*i. e.* for a shunt machine thicker wire could be used, or for a series machine thinner wire), or that the heat radiating or external surface of the whole coil (not of the wire itself) may

Digitized by Google

be smaller, and as the diameter of the coil is larger it shows that the length of the coil could be less. Knowing the periphery of the core, the size of the wire, and the number of ampere turns, and assuming a certain thickness or depth of coil, the length of core necessary to contain this wire can readily be calculated. This subject of the winding of magnets and length of core will be further discussed in the next chapter.

The types of field magnet frames now in common use and having only two active poles, may be divided into the four following general classes, shown in figures 25, 26, 27, and 28, in which the coils are marked *m*. They are classified here with reference to the relative position of the magnets proper, their pole pieces and their yoke pieces. Any other modifications of these general types are considered as details which do not effect the general classification.

The form shown in figure 25, consisting of a single U magnet with two coils, is probably the oldest type. It was used in the old machines of Wilde and Pacinotti. It is the form used at present in the Edison, Hopkinson and Jurgensen machines, and when the yoke piece is also covered by the coils it is the form used in the Sir Wm. Thompson and the Mather machines. For the same amount of magnetism in the armature field, the only advantage in covering the yoke piece with coils, is a slight saving of iron and of wire, as it is evidently a more economic disposition of the wire and iron, but it is accompanied by increased difficulties in winding. The type shown in figure 25, is better adapted for Gramme ring armatures than for cylinder armatures, as the field is not always perfectly balanced, being stronger on that side of the armature nearest the yoke piece. The difference may, however, be made very slight.

Fig. 25

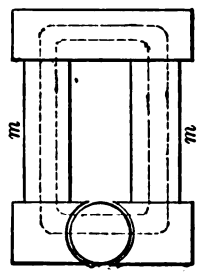

Fig. 26

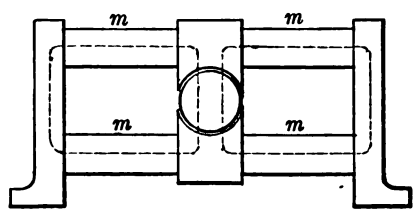

Fig. 28

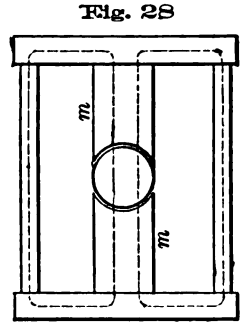

Fig. 27

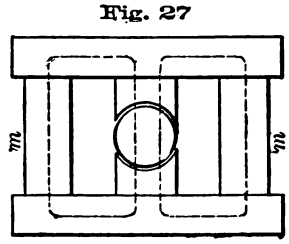

The more common type, shown in figure 26, consists of two U magnets with their like poles together. For the same magnetism in the armature, the cores and yoke pieces need be only about half as large in cross-section, as they would have to be in figure 25, as the lines of force, shown in dotted lines, divide evenly between the two U magnets. The quantity of wire being approximately the same, the length of the cores could be made somewhat shorter than in the type shown in figure 25, thus shortening the path of the lines of force and therefore the magnetic resistance offered by the iron. As it is desirable to have this magnetic resistance as small as possible, this feature of shorter circuits is an advantageous one. The field may evidently be perfectly balanced. This type is the most common, being used in the old and new Gramme machines, the Weston, Brush, Siemens, Maxim, Burgin, Crompton, Patterson-Cooper, Kapp, Jenney, Western Electric, Daft, Ball, Schuyler, Clark, Wood, Heinrichs, Knowles, Westinghouse, Consolidated company, and no doubt numerous others.—When the yoke pieces are likewise covered with coils, this type includes the Ewell-Parker frame.

The type shown in figure 27 is closely allied to this one, the two coils of each U magnet being combined together into one, and placed on what is the yoke piece in figure 26. Comparing it with figure 25, it will be seen that the lines of force generated by one coil in figure 27, do not have to pass through the other coil, as they do in figure 25, and therefore the cores can be made smaller, each coil saturates only its own core and not that of the other coil. If this were the only thing to be taken into consideration, the cores in figure 27 need be only half as large in cross-section as those in figure 25. The length of wire required will, however, affect this dimension on account of the limited length of the cores which, in this type is dependent on the size of the armature and other dimensions. Comparing it with figure 26, it has the advantage of having only two coils instead of four smaller ones. The circuit of the lines of force and therefore the magnetic resistance, may also in many cases be made smaller in figure 27 than in figure 26 ; there would probably also be a saving of iron. The objection to this form is, that, unless the distance from the pole-piece to the coils is quite large, many of the lines of force will leak directly back into the cores, and as these do not pass through the armature they are wasted. This type is used in the McTighe, Hopkinson, Griscom, and Joel machines.

The type shown in figure 28 may also be considered as two U magnets shaped like the path of the lines of force, as shown, with the coils around their common pole pieces. It has the same advantage in having only two coils, but unlike figure 27 they saturate each other's cores, as in figure 25. It generally has the disadvantage of having a very long circuit for the lines of force, it being considerably over four times the length of a coil ; this, however, is partially overcome by the fact that the coils may be made thicker and, therefore, shorter in this type than in the others. It is like figure 26 and 27 and unlike figure 25, in the feature that the field may be perfectly balanced. It is like figures 27 in the fact that there generally is great leakage of the lines of force from the pole pieces to the yoke pieces. Among the machines using this type are the Thomson-Houston, Van Depoele, Hochhausen, Kapp, and in general most multi-polar machines, as for instance, alternating current machines of the ordinary types.

Fig. 29

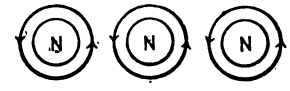

Fig. 30

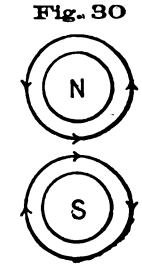

In some of the older forms of machines several small parallel magnets with common pole and yoke pieces were used in place of one larger magnet. The best known machines of this kind are the Edison "Jumbo" and the older Weston machines. Such magnets were, however, soon abandoned by the makers. They take up much more space and require a much larger amount of wire, the wire on those parts of parallel coils which face each other, being disposed so as to neutralize the magnetic effect of those

Digitized by Google

parts. This may be seen from figure 29 in which three such magnets are shown in cross-section; the current flowing around them as shown, it will be seen that the parts of the coils nearest each other tend to neutralize one another, as the neighboring currents are in the opposite direction, thereby destroying their magnetic effect. These portions of the wire are, therefore, inactive magnetically, being mere dead resistance. In such a composite magnet it can readily be shown that there are lines of force between the magnets running parallel to them, but in the opposite direction to the useful lines in the magnet cores. These are, of course, wasted, as they do not pass through the armature.

It is often supposed that two parallel magnets forming one U magnet as in figures 25 and 26, are subject to this same objection, and that, therefore, the coils should not be too near together. But this is not the case, it is on the contrary an advantage to bring them as near together as the nature of the frame will permit. This will be seen from figure 30, which shows the cross-section, perpendicular to the cores, of the two parts of one U magnet in figure 25 or 26. It will be seen that the currents in two neighboring wires of the two coils must be in the same direction, in order to develop the two opposite poles at the ends of the magnets. The currents in the upper half of the lower coil are, therefore, in the right direction to act with those in the upper coil to saturate the core N, and *vice versa*. In other words, each coil tends to saturate the core of the other coil, as described in another part of this chapter. It is, therefore, an advantage to bring such magnets quite close together, provided they are not so near as to allow the lines of force to leak directly from one to the other near the pole ends.

The shape of the pole pieces around the armature has already been discussed in the chapter on armatures. The air space between the pole pieces and the armature core should be made as large as possible in area, and as thin as practicable. It is not the case, as is sometimes claimed, that according to the law of inverse squares, the intensity of this field will be inversely as the square of the distance between the iron. That is a misinterpretation of the law. The field does become weaker as this thickness increases, but as Deprez has shown, this decrease in strength is much smaller than is generally supposed.

As described before, the pole-piece projections should not be too near to each other, and they should not be too near to any other iron parts on account of leakage. They should be rounded off on their outside edge to avoid the tendency to leakage from the sharp edges. It should be remembered that these projections are often the most intense parts of the field. It is probably an advantage to incline the edges of these projections instead of making them parallel to the axis, in order to cause the wire to enter the field gradually instead of suddenly.

For cylinder armatures, it is important to have the field well balanced magnetically, that is, to give it the same intensity per square inch throughout, or else to have it symmetrical with respect to the axis, on both poles. This is not so important for Gramme armatures, but it is essential for these and for most cylinder armatures to have the same number of lines of force in both pole pieces, and to have the wires cut them at the same speed, otherwise there may be local currents in the armature as described before. It is, therefore, necessary to avoid unsymmetrical leakage, as for instance, from one pole-piece through half the armature, and returning through the shaft and the single iron bearing support, back to the magnets; such lines are cut by only one side of the armature.

Accessory iron parts of the frame or base plates, should be as far removed from the pole pieces as possible, to avoid leakage. For the same reason braces or bearing supports should not be fastened to pole pieces, or else should be made of brass. If for convenience they are of iron and are fastened to the pole pieces, they should be symmetrical and be separated as far as possible from each other.

ELECTRICAL DISTRIBUTION BY ALTERNATING CURRENTS AND TRANSFORMERS.[1]

BY RANKIN KENNEDY.

I.—SYSTEMS.

The distribution of electric energy for electric lighting on a commercial scale is a problem which has not yet been practically solved; the chief difficulty in the way of wide and extensive distribution lies in the low potential necessary for the working of the present forms of lamps; 100 volts may be taken as the standard of pressure at which we now distribute electric energy on the small scale in isolated electric plants. The pressure being small a very large volume of current is required to convey a moderate amount of energy for distribution; large currents require large conductors, and when the question of distributing, say, 20,000 electric lamps of 16 candle-power each arises, we are at once met with the difficulty of laying main wires sufficiently large to convey the energy in the large volume of current necessary for this comparatively small number of lamps.

This difficulty in the way of direct supply at low pressure was early recognized by electric lighting engineers, and many proposals have from time to time been made to obviate the difficulty by distributing the energy at high pressure, and devices have been invented for reducing this high to a low pressure on the consumers' premises to suit the requirements of the low-pressure lamps.

One method, early proposed and put into practice by several inventors, is based upon the fact that alternating currents or intermittent currents of electric energy can be easily and economically converted or transformed from currents of high pressure and small volume to currents of low pressure and large volume and *vice versa* by means of induction coils.

This method is now attracting considerable attention and has met with considerable success in the hands of later inventors; a great many electricians are actively prosecuting enquiries into the construction and functions of the improved induction coils, and no doubt the subject deserves attention as a means of extending the development of electric lighting.

In these papers it is proposed to examine into all the proposals made and put into practice during the last 10 years, and thus obtain a knowledge of the history of this method of distribution by high-pressure alternating currents and induction transformers. The patent records may be taken as a very good history of any important electric system now in operation, and a short notice of each of the patents applied for during the last 10 years, together with a description of the systems now in practice, to be followed by a description and history of transformers, will, it is hoped, be interesting to electricians and others.

In 1877, Mr. P. Jablochkoff obtained a patent for a method of working electric lights by induction coils, to be actuated by an alternating current or by a continuous current, rendered alternating by a commutator or intermittent by an interruptor; this patent contains the elements of a system of distribution by induction coils, namely, a generator of alternating or intermittent currents—a main conductor forming a main circuit in which is placed any number of induction coils, and lamps or other translating devices placed in the secondary circuit of the induction coils. Apparently, Jablochkoff wanted a high-tension current in the secondary circuit for the working of his kaolin lamps, and, therefore, we may presume the secondary current employed by him was higher than the

1. From the *Electrical Review* (London).

Digitized by Google

primary in pressure, but this does not necessarily follow. The induction coils are placed in series order in the circuit.

C. W. Harrison, of London, obtained a patent, No. 3,470, 1878, for the use of induction currents for providing electric lights; this appears to be a series system similar to Jablochkoff's.

Patent No. 4,219, 1878, was granted provisionally to Sir C. Bright for a system of distribution by induction coils. This specification is very vague. In this patent we have the same elements as indicated in Jablochkoff's. A generator of alternating or intermittent currents—a main conductor to convey the current—induction coils at each point where the light is required.

Like Jablochkoff's, this system appears to have been designed to supply high-tension currents for the special high-tension lamps mentioned in the specification, there being no low-tension lamps in existence at the date of this patent. It must be admitted by electricians that this and Jablochkoff's system are equally competent to supply low-tension currents in the secondary circuit, and this is indicated in Bright's patent by the sentence, "The size and length of the primary wire and secondary wire coils are adapted to the number of lights employed."

Whether the induction coils are to be worked in parallel or series is not stated. "*They are connected to a metallic main conductor common to all.*" This may mean anything, but the use of the singular number—*a conductor*—would indicate a series order of connection to most electricians.

Patent No. 4,611, November, 1878, granted provisionally to Mr. Edmund Edwards and Alphonse Normandy, is a most important one.

This patent is quite clear and distinct. The elements of the most complete system of distribution by alternating currents and induction coils placed in series order in the circuit are clearly set forth in every detail, even to the working of a second induction coil from the secondary circuit of another coil in the primary circuit. As a system of distribution with the induction coils in series order we shall find that no improvement on the proposals made in this patent have been made by any subsequent inventors, and, therefore, this specification may be taken as a good description of the series system of working induction coils.

But, like all prior and subsequent proposals to work transformers in series order, it presupposes that there is no disturbing action in the transformers themselves, and no provision is made for regulation or independence of action in the transformers.

Patent No. 5,183, December, 1878, granted to J. B. Fuller, of New York, U. S. A., contains all the elements of a system of distribution by induction coils and alternating currents; in this patent we have for the first time a regulating device clearly indicated. "A pivoted arm regulates the light by strengthening or weakening the magnetic field."

Patent 5,257, December, 1878, granted to A. de Meritens, of Paris, is for a system very similar to that of Edwards and Normandy, and is quite complete as a series system of distribution although it makes no advance on the prior inventions.

The same system with the same features was again introduced in 1882 by Messrs. Gaulard and Gibbs. In the system described in the patent of these gentlemen we have all the elements arranged precisely as in the systems patented or described by Jablochkoff, Edwards and Normandy, Bright and de Meritens. The transformers are arranged in series order, fed from a high-tension dynamo supplying constant current and with a variable E. M. F.

In 1884 these same inventors patented the series system again; in this specification an attempt is made to prove that the transformers connected in series to the supply at constant current shall be self-regulating and act independently of each other if constructed according to the description given therein.

Whatever the value of the Gaulard and Gibbs systems as described in their specifications, these gentlemen promoted the application of the transformer to electric lighting by coming prominently before the public and undertaking electric lighting on their systems.

Their proposals were criticised by some, scoffed at by many, and altogether ignored by the majority of electricians; they, however, stuck to their colors and replied to criticisms in the *Electrical Review* of the time.

In June, 1883, these discussions drew out some letters in which I indicated the impossibility of self-regulation and independence being obtained in any system employing transformers in series order with constant current supply. For the first time the actual effects of counter E. M. F. were described, and the first letter concluded by stating that if transformers or secondary generators were connected in parallel order they then became beautifully self-regulating.

In the *Electrical Review* of that time a leading article on the subject appeared, in which it was prophesied that these conclusions of mine would be followed up by others. This prophesy was soon fulfilled by a patent being applied for by Max Deri and Carl Zipernowski, of Buda Pesth, in which the transformers are to be placed in parallel order; Messrs. Gaulard and Gibbs did not, however, take up this matter, for we find them with another patent, in 1884, for a series system of distribution.

The perception of the action of the counter forces in the transformers and the connection of them in parallel order to the mains was a great step in the history of the distribution of electric energy by alternating currents and transformers; success which had been denied every attempt to work them in series was at once obtained when they were put into parallel connection, and the counter forces which had caused all the disturbances when in series were now employed for the automatic regulation of the whole system; before leaving the series system and examining the parallel, it may be stated that no self-regulating transformer of alternating currents has been invented up to this date which will give constant E. M. F. in the secondary circuit with constant current in the primary circuit.

"As the current in the secondary circuit increases, the counter E. M. F. in the primary *decreases*, and therefore the current in the primary circuit increases." That is the law of the alternating current transformers, and the fact of this law governing them, at once renders them perfectly adaptable to connection in parallel order to a supply at constant E. M. F.

For successful working in series order the transformers should conform to an entirely different law which would read: "As the current increases in the secondary circuit, the counter E. M. F. in the primary circuit *increases*, and therefore the difference of potential between the ends of the primary wire or circuit *increases*."

(*To be continued.*)

ABSTRACTS AND EXTRACTS.

ON THE DETERMINATION OF THE COEFFICIENT OF SELF INDUCTION.

In order to measure the coefficient of self-induction of a bobbin without iron and having but few turns of wire, say MM. Ledeboer and G. Maneuvrier in *Comptes Rendus*, we make use of the following method:

The resistance bobbin, R, the self-induction co-efficient, L, of which is sought, is arranged in electric equilibrium in a Wheatstone bridge used in the form of a graduated wire bridge. The slide having been brought to the middle of the divided wire, the equilibrium is made by means

Digitized by Google

of a nickel-silver wire, forming the fourth branch of the bridge. A revolving interrupter introduced into the circuit of the battery and into that of the galvanometer, transmits at each rotation the extra current of rupture into the galvanometer. We obtain thus a permanent deviation. We then eliminate the constant of the galvanometer and the intensity of the current which passes into the bobbin by making a second experiment. We stop the interrupter and we displace the slide by a small distance, ε; this destroys the equilibrium of the bridge and occasions in the galvanometer the passage of a feeble current which produces a deviation, a. We then find the coefficient of self-induction, L, by introducing these values of ε and a into the formula

$$L = R \frac{2}{l} \frac{\varepsilon}{n} \frac{1}{a} \delta$$

l being the length of the divided wire which corresponds to the resistance, R, and n the number of turns per second of the revolving interrupter.

We have verified the accuracy of this method by comparing the results which it gives for the co-efficient of self-induction of any two different bobbins with the results yielded by the direct measurement of the extra current. The following are the numbers given:

	Above method.	Direct method.
1st bobbin R = 0.122 ohm.	L = 0.00101	0.00102 ($\times 10^9$ cm.)
2d bobbin R = 0.431 ohm.	L = 0.00142	0.00143.

We have found, besides, that on substituting a straight wire for the bobbin, no appreciable deviation is produced on turning the interrupter.

We have applied this method to the measurement of the coefficients of self-induction of a Siemens electro-dynamometer and we have found the following values:

	R. Ohms.	L. 10^9 cm.	$\frac{L}{R}$
Thick wire (entire apparatus)..... ..	0.010	0.0000035	0.00035
" " (fixed coil alone).....	0.0060	0.0000023	0.00038
" " (movable coil alone).....	0.0040	0.0000012	0.00031
" " (entire apparatus).....	0.431	0.00142	0.0032

The movable coil of the apparatus has only four turns of wire; the fixed coil has seven turns of thick wire.

These numbers are available for the verification of the following fact. In the Siemens electro-dynamometer, the movable bobbin has its axis perpendicular to that of the fixed bobbin, and the current traverses the two bobbins in series. Hence it results that the mutual induction between these two bobbins is nul, and that the coefficient of self-induction of the entire apparatus should be the sum of the coefficients of self-induction of the two parts.

This is, in fact, verified by the numbers just obtained. In particular (as happens approximately in this case) when the ratios $\frac{L}{R}$ are equal for the two bobbins, separately, calculation shows that we must have the same value of the ratio for the entire apparatus. Now this ratio, $\frac{L}{R}$, has here the value of 0.00038 for the fixed frame, 0.00031 for the movable frame, and 0.00035 for the entire apparatus.

We know that this relation intervenes in the case of the measures relating to alternating currents, and it is with the view of studying these currents that we have undertaken these preliminary experiments.

As will be seen, our method consists in a novel adaptation of the known methods of Maxwell and of Lord Rayleigh to the particular case where the current is too feeble to give an appreciable impulse to the galvanometer. It presents the further advantage of rendering the use of a ballistic galvanometer unnecessary, and of rendering the employment of an ordinary mirror galvanometer possible and practicable. We prefer it to the other methods of measuring weak coefficients of self-induction, and especially to the method of M. H. F. Weber (a modification of that of Mr. Hughes), because it leads to a very simple formula and because it requires, except the Wheatstone bridge, no other experimental appliance than a rotary interrupter.—*Electrical Review* (London).

ON A SIMPLE AND CONVENIENT FORM OF WATER BATTERY.[1]

BY HENRY A. ROWLAND.

For some time I have had in use in my laboratory a most simple, convenient and cheap form of water battery, whose design has been in one of my note-books for at least 15 years. It has proved so useful that I give below a description for the use of other physicists.

Strips of zinc and copper, each two inches wide, are soldered together along their edges so as to make a combined strip of a little less than four inches wide, allowing for the overlapping. It is then cut by shears into pieces about one-fourth of an inch wide, each composed of half zinc and half copper.

A plate of glass, very thick and a foot or less square, is heated and coated with shellac about an eighth of an inch thick. The strips of copper and zinc are bent into the shape of the letter V, with the branches about one-fourth of an inch apart, and are heated and stuck to the shellac in rows, the soldered portion being fixed in the shellac, and the two branches standing up in the air, so that the zinc of one piece comes within one-sixteenth of an inch of the copper of the next one. A row of 10 inches long will thus contain about 30 elements. The rows can be about one-eighth of an inch apart, and therefore in a space 10 inches square nearly 800 elements can be placed. The plate is then warmed carefully so as not to crack and a mixture of beeswax and resin, which melts more easily than shellac, is then poured on the plate to a depth of half an inch to hold the elements in place. A frame of wood is made around the back of the plate with a ring screwed to the centre so that the whole can be hung up with the zinc and copper elements below.

When required for use, lower so as to dip the tips of the elements into a pan of water and hang up again. The space between the elements being one-sixteenth of an inch will hold a drop of water which will not evaporate for possibly an hour. Thus the battery is in operation in a minute and is perfectly insulated by the glass and cement.

This is the form I have used, but the strips might be better soldered face to face along one edge, cut up and then opened.

THE EFFICIENCY OF ELECTRIC MOTORS.

A number of experiments, says *Engineering*, of London, have been made by Mr. W. M. Mordey and Mr. C. Watson, at the factory of the Anglo-American Brush Electric Light Corporation, to find out the best principles on which to construct electric motors, and the reason why the dynamo as a motor should have a lower efficiency than when working as a generator. As given in the *Philosophical Magazine*, these principles are: 1. That the magnetic field should be a very strong and the armature a very weak electro-magnet. 2. In both generators and motors lead, distortion or displacement of the brushes or the magnetic field is wrong, and is to be avoided by attention to the first condition. If there be any lead in dynamos it is in the direction of rotation; in motors it is in the opposite direction, as the course of the current through the armature is reversed; but the field is the same. 3. In both generators and motors absence of sparking at the brushes depends mainly on the first condition being complied with. 4. Reversal of rotation. In neither generators nor motors

1. From the *American Journal of Science*, February, 1887.

Digitized by Google

is movement of the brushes necessary. It appeared from these principles of construction, which are applicable to both generators and motors, that the lower efficiency of the dynamo as a motor must be due either to friction at the bearings, air friction, and friction of the brushes against the commutator; to loss of energy in heating the armature and field magnets, and to self-induction; or to loss by the production of eddy currents in the iron. From the nature of these probable causes consideration shows that the last is the true one; for in a dynamo the rotation of the armature causes eddy currents to be generated in the iron core in the same direction as the conductor proper with which the core is surrounded. Of course, as the armature is always more or less sub-divided or laminated in a direction at right angles to the line of force, any circulation of currents round the core is avoided; but local currents or "eddies" are set up, and taken as a whole these eddy currents on the outside of the core are in the same direction as the current flowing in the copper conductor. In an electric motor, however, the eddy currents and the currents in the copper conductor are in opposite directions, as, although the electromotive force set up in the conductor is in the same direction in a motor as in a dynamo, the current in the former is forced through the armature in a direction contrary to the electromotive force. It will be seen that while in a dynamo the two sets of currents, those in the iron and those in the conductor, tend to oppose and to reduce one another, in a motor they act in such a manner as to mutually assist one another. Thus, with the strength of field, the current in the conductor and the speed the same in both cases, the eddy currents in the iron core of the armature will be greater than in a generator, and the loss from heat more.

THE EMPLOYMENT OF SPIRAL SPRINGS FOR MEASURING INSTRUMENTS.

In a paper by Prof. W. Kohlrausch, in the *Electrotechnische Zeitschrift*, on the employment of spiral springs, for measuring instruments and the accuracy of galvanometers constructed therewith, the causes which are likely to affect the constancy of spiral springs are mentioned in detail by the author, with an account of experiments bearing on each point, in order to afford some idea of the reliance that can be placed on the indications of instruments into the construction of which they enter. The effect of age, judging by observations on a brass spring extending over a period of seven years, may be completely neglected. Continuous and prolonged deformation produces a small amount of permanent set, so that the spring, when released, does not return to the original position, but does not actually alter the indications of the instrument if the readings are taken from the new zero thus found; steel is, in this case, less affected than German silver. Oft repeated, but intermittent deformation—as exhibited by a spring of 90 convolutions and 2½ inches long, being stretched so as to change from a length of 3½ inches to 9 inches 200 times per minute for 400 minutes—introduced no appreciable alteration in its subsequent indications. An increase of temperature of 18 degrees Fahrenheit raised the indications of a Siemens' torsion galvanometer about one-tenth per cent., so that the reduction in the elasticity of the spring is apparently almost equal to the decrease in moment of the magnet, which would be, under these conditions, about 0.4 per cent. Further experiments on loaded springs confirmed this conclusion, and showed that steel was again to be preferred to German silver. By combining the results given above, the utmost limit of error introduced by the use of spiral springs cannot exceed 0.5 per cent. If, however, as is the case in the Siemens' torsion galvanometer, the current passes through the spiral spring, care must be taken that the heating from the passage of the current is not excessive. The author found an alteration of 1.4 per cent. in the indication of such an instrument after a continuous test of 30 minutes, with a difference of potential of 100 volts between the terminals. If such instruments be calibrated at intervals to correct the decrease in the moment of the magnet, an accuracy within about 0.1 per cent. can be relied on. With the Siemens' dynamometer for intense currents, the limit of error, owing to the friction at the mercury contact, is about 1 per cent. Another form of instrument, the spring galvanometer of F. Kohlrausch, is also reliable within 1 per cent., and is perfectly aperiodic with frictionless damping. Owing, however, to the employment of an iron core, the readings of currents taken in ascending and descending order of magnitudes will vary to some considerable percentage from the effect of residual magnetism, which exists in even the best soft iron, if this error be not eliminated by mechanically bringing the core past the position it would take up under the action of the current, and then leaving it free to return to that position.—*The Electrician* (London).

LIGHTHOUSE ILLUMINANTS.

Another bulky blue book on the subject of lighthouse illuminants has just been issued by the board of trade. It consists principally of correspondence which has taken place between the department, the Trinity House and various shipowners throughout the country. The actual value of electric light for lighthouse purposes is still a matter of dispute. The report of the Trinity House committee, which investigated the whole subject two years ago, has not been accepted as final. The opposition is, doubtless, to some extent, factitious, arising from those whose interests are affected, while to some extent the complaints of pilots as to the dazzling effect of the beam may be well founded. The idea, however, which is still industriously promulgated, that the electric light has less power than gas or oil of penetrating fog was thoroughly disproved by the experiments of the committee, who, it may be as well to repeat, summed up their report in the following terms: "That the electric light, under all conditions of weather, is the most powerful, and has the greatest penetrative power in fog," and "That the Trinity House recommended mineral oil as the most suitable and economical illuminant for the ordinary necessities of lighthouse illumination, and that for important land falls, where very powerful light is required, electricity offers the greatest advantages."—*The Electrician* (London).

ELECTRIC LIGHTING AT THE PARIS EXHIBITION OF 1889.

The finance commission of the proposed International exhibition in 1889, under the presidency of M. Lockroy, has settled the main features of the electric lighting of this exhibition. The conclusions arrived at by the committee were based upon the proposal made by five of the largest electric light firms in Paris, representing a total share capital of £510,000. The point of special interest to English and other foreign manufacturers, and would-be exhibitors, is an attempt, on the part of this syndicate of French manufacturers, to get the whole of the lighting under their control. Their proposal amounts to nothing less than to farm out the lighting, they to be responsible to the executive commission of the exhibition for the proper carrying out of the work. It is doubtful whether English electricians will fall in with this arrangement, which would require them to put their interests into the hands of a syndicate consisting mainly of trade rivals. But this is practically what the syndicate wish to bring about, since, in their recommendation, they say that in order to carry out the work of lighting in a proper and efficient manner the signatories are ready to form a syndicate, and to admit into this syndicate all exhibitors of

Digitized by Google

electric lighting appliances, without distinction of nationality, provided they adhere to the conditions imposed by the executive committee, and to the rules and regulations of the syndicate. All exhibitors who join on these terms, will participate, in like manner, in any benefit which might arise from this undertaking. It is proposed that the executive committee should hand over to the syndicate one-half of the entrance fees received between the hours of 6 and 11 P. M.; the entrance fee to be two francs for that time, whilst the usual fee during the day is only one franc. No reduction in the entrance fee in the evening is to be made by the executive committee, without having obtained permission from the syndicate. The total amount of light to be provided is estimated at close upon 3,000,000 candles, and the power at 3,000 h. p., with an additional 1,000 h. p. reserve. The light is to be partly arc and partly incandescent, but the proportion between the two is not given. This, however, can approximately be calculated from the above data. Roughly speaking, the power for the incandescent lighting will amount to 1,660 h. p., and that for the arc lighting to 1,340 h. p. It will thus be seen that the incandescent lighting is not such a gigantic enterprise after all, and it is about of the same magnitude as the whole of the lighting was at the Colonial exhibition in London.—*Industries.*

UNDERGROUND TELEGRAPH WIRES IN GERMANY.

THE question of overhead against underground telegraph wires has again excited public attention, in consequence of the breakdown occasioned by the recent snow storms, and in several quarters the example of Germany was cited as one which should be followed by our own postal authorities. As the statements which appeared in various daily papers and periodicals were at variance with each other, and left the whole matter in an undecided state, we asked our electrical correspondent in Berlin to collect some information on the question of subterranean lines in Germany, and he writes as follows: "According to the plans elaborated by the German post office, the underground cables were intended, in the first instance, to serve for direct communication betwen the more important centres of business throughout the empire, and are, therefore, strictly speaking, commercial lines, military considerations being of secondary importance. Intermediate stations on these great trunk lines are very seldom connected to them, and the traffic to or from intermediate points goes by overhead wires. In certain cases, where it is desirable to divide the trunk into several sections, worked by relays, these are placed in intermediate stations, which can then also speak to the large centres by means of the underground cables; but this use is exceptional. The cables throughout the whole system, serve only for the outgoing current, the return circuit being through earth, as usual. Each cable serves for seven circuits, each of these consisting of a seven-stranded copper cable, insulated with gutta-percha. The diameter of the single wire varies, according to the length and importance of the line, between 24 and 28 mils. The cables are protected by an iron wire covering, and are placed without any further preparation into trenches about three feet deep, which are then filled up. The instruments used on the underground trunk lines are practically the same as those serving for the overhead lines; but special apparatus has been added, to reduce, in a certain measure, the retardation due to static induction. Up to a distance of 240 miles there is no difference in the speed between overhead and underground lines, when worked with Morse instruments; and even greater distances are worked with these instruments, by the addition of the apparatus above mentioned. At 360 miles, from 300 to 330 currents can be sent per minute; but when the distance is considerable, the post office prefers to insert relays, which work very satisfactorily. Besides the Morse, the Hughes apparatus is much used; but certain additions and alterations had to be made to the original pattern, in order to render it fit for long-distance service. The speed on our lines is, according to English ideas, exceedingly slow, the average being only 16 words per minute. An interesting and useful addition to our telegraphic system lies in the stations for periodical testing of the lines. In 18 junctions of our telegraph net-work are erected special testing rooms, in which the underground cables are tested weekly, at a predetermined hour. The tests are thus performed in the two end stations of each trunk line almost simultaneously, so that each portion of the line is tested independently and at the same time by two observers. From Berlin radiate eight large underground trunk lines." It will be seen from the report of our correspondent, that although the service is organized with the thoroughness usual to the German official mind, and evidently works to the entire satisfaction of its customers, yet a similar telegraph service would be totally inadequate to deal with the enormous business transacted over our English lines. In Great Britain, speeds up to 300 and even 400 words a minute are not at all unusual, and have even been obtained on lines which are partly sub-marine, such, for instance, as the lines between England and Ireland. To come back from these speeds to the ridiculously slow rate of 16 words per minute, would certainly be too high a price to pay for the advantage of having underground lines, and this is a point which seems to have been entirely overlooked by those critics of our postal telegraphs who seem to think that these things are better done in Germany.—*Industries.*

INDUCTION COILS OR TRANSFORMERS.

THE following interesting letter from Prof. Elihu Thomson appears in the *Electrical Review* of London, for April 15th.

"I have been much interested in reading the historical matter connected with the distribution of alternating currents by induction coils or transformers, contributed by Mr. Rankin Kennedy, and the first part of which appears in your issue of March 18th, 1887."

I think it will be of interest to your readers and useful in the history of the subject if I state the following facts:

On November 8th, 1878, I filed in the United States patent office, jointly with Prof. Houston, an application for a patent for an induction coil system in which the secondary wires of the induction coils differed from those of the Ruhmkorff coils in being made of coarse wire instead of fine wire, and used to run vibrating arc lamps, which application was rejected on the ground that there was no invention in substituting coarse for fine wire in the secondary.

On January 13th, 1879, a description, which is still in my possession, was written out and dated, describing and showing by drawings the connection of the coils in multiple arc from a main line, with vibrating arc lamps operated by the secondary currents. It was recognized at the time that the working of one branch would not, with a constant potential between the mains, affect the work in the other branches. In February, 1879, having completed an alternating current dynamo, a pair of induction coils were connected in multiple from the mains running from the machine, and the arrangement tested. The coils used were such as are described in the *Franklin Institute Journal* of January, 1879, in which the two conductors were surrounded by a sheath of divided iron, and the testing was done at the institute, the engine there furnishing the power for the dynamo. This was before the day of incandescent lamps, and as several years elapsed before such lamps could be freely purchased, there was, in 1879, no market for an induction system.

My time has been so completely occupied with various developments in the field of electric lighting that I have hesitated to enter into any of the discussions on these matters which have appeared from time to time, and I make the above statement feeling that it is right and proper under the circumstances.

I notice also in your issue of March 18th 1887, a paragraph accredited to *Industries*, saying that "La Société pour le Travail Electrique des Meteaux" had bought up all the patents connected with electric welding, and other applications for working metals by electricity. This is somewhat interesting to me, as I now happen to hold some patents connected with the subject.

STENO-TELEGRAPHY.

SOME of the features of short-hand writing, synchronous-multiplex telegraphy and type-writing, are combined in a

Digitized by Google

system of steno-telegraphy invented by M. G. A. Cassagnes, of Paris. In recent experiments over a wire running from Paris to Orleans and back, messages were sent at the rate of two hundred words a minute, that being the highest speed attainable by a nimble-fingered operator. By means of an automatic transmitting apparatus, using a strip of paper previously perforated, as in some of the systems of telegraphy already in vogue, 17,000 words per hour were sent over a line 650 kilometers in length, the messages being automatically printed by the receiving instrument.—*Science.*

COPPER PRODUCTION OF THE UNITED STATES.

THE following statement of the copper production of the United States for 1886, has been prepared by Mr. Charles Kirchhoff, agent of the United States Geological Survey for the division of mining statistics: The total production of the year was 156,373,421 pounds of domestic copper, produced as follows: Lake Superior, 79,728,838; Arizona, 15,657,035; Montana, 57,611,621; New Mexico, 558,385; California, 430,210; Colorado, 409,306; Utah, 300,000; Nevada, 50,000; Maine, New Hampshire and Vermont, 315,719; Southern States, 29,811; lead desilverizers, etc., 1,282,496 pounds. Not less than 136,820,943 pounds were turned out by American refining works, including a small quantity of blister exported as such, and small amounts of unrefined copper going directly to consumers. Deducting from this the exports, 19,504,087 pounds, there remains over 117,000,000 pounds available for home consumption, of which about 64,000,000 pounds came from Lake Superior and the balance, 53,000,000 pounds, from other sources. The important features in the copper trade of the United States in 1886 have been the continued increase in the output of Lake Superior and the falling off of Arizona and Montana; the sharp decline in the quantities exported, and, above all, the notable increase in the quantity of copper which sought the more remunerative home market. Coupled with this tendency to overstock the home trade in the face of a declining output, is the important fact that the quantity of miscellaneous grades has improved, and that consumers have learned to utilize relatively lower grades of copper. While the local supply has increased, the consumption in this country, has, on the other hand, developed a gain in the most satisfactory manner.—*American Engineer.*

SOME INTERESTING EXPERIMENTS WITH STATIC ELECTRICITY.

THE following interesting experiments, which will probably be new to many of our readers, were described by Mr. Boys at a recent meeting of the Physical Society:—"If sealing wax or any similar sticky substance, be melted in a cup and put upon the conductor of an electrical machine, as in one of the old fashioned experiments, it will begin to throw out threads in an extraordinary way; the fibres are large when the resinous matter is very hot, each fibre shoots out as a cylinder with remarkable speed, then breaks into beads. These minute beads can be made to patter against a drum head, and make a noise upon it like falling rain. The cup containing the melted wax should be inclined from the operator and from the electrical machine before the latter is worked, or both will be covered with the most invisible sticky web imaginable; a cup of burnt india-rubber tubing so treated sends out almost invisible filaments. Canada balsam is the perfection of a material for producing such sticky threads. When a candle is held near a cup throwing out such electrical filaments they shoot into the flame and sometimes cover the candle; sometimes they will stop as they approach the flame, then turn back, and go into the cup from which they started, in consequence of discharging their electricity into the flame. In a few minutes miles of these sticky threads can be made, and as they break into beads the method affords a ready means of powdering such of these substances as are not easily pulverized in any ordinary way."—*The Electrician* (London).

INFLUENCE OF ELECTRICITY ON DELICATE WEIGHING.

M. HENNIG DE WURTZBOURG having noticed some incomprehensible differences in the weights of equivalent quantities, undertook investigations, which showed that balances of precision are often influenced by the electric state of the glass case which surrounds them. This electricity influences the "riders" which slide on the beam of the balance. The error resulting from this influence may amount, it is said, to 600 milligrammes where the case is strongly charged, and two hours afterwards there may still be an error of 10 milligrammes.

THE GERMAN PATENT OFFICE.

ACCORDING to the official report of the German patent office, just published, the number of applications for patents rose from 5,949 in 1878, to 9,991, in 1886; but whilst in the former period only 25 per cent. of the applications were disallowed as not patentable, they increased in the latter to 60 per cent. In 1886, 4,008 patents were sealed, whilst 5,983 were disallowed.

GAS AND ELECTRICITY.—TWO INTERESTS OR ONE?[1]

GEO. W. GRAEFF, JR., PHILADELPHIA.

THE time has certainly come when the discussion of this question is imperative, and when it must be held with view to business prospects only. Prejudice and sentiment must alike be given to the winds, and the cold test of dollars and cents be applied, without fear or favor. The question is a business one, solely.

Since the introduction of electric lighting as a means of artificial illumination, until within the past few months, there has been little between the gas and electric interests in this country, save direct and unreasonable antagonism. Some of the reasons are plain.

For many years gas had occupied the field as the general and practical artificial illuminant for domestic and commercial uses. From a small beginning, the business grew into a settled and conservative industry, inferior in commercial importance and as a field of financial investment, to the railroad and mining interests only. The combined capitalization of the gas companies of the United States runs high into the hundreds of millions, as figures easily show.

While in its earlier years, the industry of gas manufacture met with many obstacles and encountered conflicts and setbacks in its struggles for recognition and success in the business world, its growth has, altogether speaking, been rapid and enormous. With success, it became more and more conservative in its methods, and finally grew to look with anger and jealousy upon any proposed interference with what it considered its vested rights in the control and monopoly of the business of artificial illumination. It is not strange, therefore, that the introduction of the electric light, some half-dozen years ago, met with jealous protest and vigorous objection from the gas fraternity. Nor were these sentiments subdued by the methods by which many of the electric light advocates began the endeavor to force their systems upon the public.

Like nearly all other inventions of promise, the electric light was seized upon by speculators, in many instances for the organization of companies that were thrown upon the public as ventures. Failures followed and were numerous, as was to be expected. Both upon the other side of the Atlantic and on this, schemes, gigantic chiefly in their paper capitals, collapsed, and when inflated ventures came to grief, the public was swift to condemn the entire industry as fraudulent, oftentimes to the great prejudice of earnest and honest men who were devoting time, talents and money to the development of the new system, in their endeavors to place it upon a sound commercial basis.

Reasoning largely from the distrust of the unconcerned world, the concerned gas companies generally throughout the country became strongly imbued with prejudiced opposition to the new means of light, presenting the constant argument that the whole affair was a mass of gigantic scheming, unworthy of

1. Paper read at the Third Annual Meeting of the Ohio Gas Light Association.

Digitized by Google

friendly consideration; while, on the other hand, its possible success meant the constant presence of a dangerous rival to the gas interests.

As if directly to increase this antagonism, many of the parent or manufacturing electric light companies persisted in exacting fabulous "stock concessions" and enormous profits upon sales of electric apparatus, and for the rights to use their several systems. In this manner, the local companies and users were handicapped with an enormously inflated capital stock, which rendered practically impossible the return of any profits to the legitimate investor, and, as a consequence, the business of electric lighting has been compelled to wade through a period of invention, development, scheming, and, we might almost add, wholesale error, such as always attaches, in a greater or less degree, to the development of new and greater enterprises wherein capital has to be sought from the world at large. The electric light manager who has labored earnestly and faithfully to reform the business from such abuses, and to place it upon a solid and legitimate commercial basis, has had neither pleasant nor easy task to perform, and has manifestly suffered from being considered to be in bad company.

During the past five years, invention has been an art assiduously plied, and the business has been greatly improved by a few earnest and determined men, who have loyally worked for legitimate development. Systems have been revised, apparatus has been improved and perfected, the cost of original production greatly reduced, and the prejudices of gas makers and their masters—the public—satisfied. The matter of electric lighting is now regarded generally by thoughtful business men, as an established and honorable industry. Despite speculation, failures and the naturally expensive cost of development, the business has made its way from the realm of venture to that of at least moderate success.

The fact of this metamorphosis has greatly changed its relations to the whole commercial world. As a substantial and legitimate investment, there is now nothing that appeals with more force to capital, when organized upon a proper basis, unless it be the industry of gas manufacture. The combination of the two in one is irresistible.

To the gas companies of the country, the electric light now occupies a higher and broader relation, and the more advanced of these have become satisfied that there should be no more antagonism between the two illuminants. They are either rivals or companions in trade, and the closer the association, the better and more profitable for both interests, and for that other factor of importance to every gas manager—the consumer. The two methods should be combined and worked together in all cases wherein artificial illumination is supplied by a corporate or private concern. The reasons for such combinations are many and potent. We give a few:

Nearly every city and town in the civilized world, containing 10,000 inhabitants or upwards, has an established and successful gas plant. The organizations of these companies are complete. They have their executive managements and labor systems in active operation. Generally such companies have a surplus of brain and sinew, that is not taxed to its full capacity, to manage the company or operate the works. In a great number of cases, the gas company could operate an electric light plant with little or no extra expense for executive and manual labor. In many instances, hardly an additional man would be needed by an established gas company, in adding electric lighting to its business,

A majority of the gas companies have more land than is actually required for the operation of their works, and not infrequently surplus room in their buildings, that could be profitably occupied by an electric light plant. This would save all rent—an item that means from $250 to $2,500 to the independent electric company.

Where a company has any difficulty in disposing of its coke at a fair figure, it can find a use for a goodly portion in the electric lighting service; and where coke meets with ready sale, the employ of the quantities necessary for such fuel purposes, would draw the line of demand more tightly and generally secure better prices for the portion sold. This, as a great soldier remarked of the tariff, is a local question.

A large proportion of the older gas companies have a surplus of earnings on hand, sufficient to pay for an electric plant. This would enable the company to sell its electric light at a considerably reduced price from that necessarily charged by an independent company, the latter of which must earn dividends upon its capital stock which will not average less than $20,000 to $30,000 for each 100 arc lamps it operates from a central station, built upon modern principles. Where additional capital is required by the gas company, the amount would be far less than that needed by an independent electric light company. The cost of installation, and the saving thus made in organization and operation, would be sufficiently large to give the gas company enormous advantages over an independent organization. These advantages, in many instances, would include the declaring of dividends when, upon the other side, none could be thought of.

It is not necessary to refer, save briefly, to the street lighting argument. It is acknowledged that arc lights in the street cause increased use of gas for interior purposes. It is evident, therefore, that this arc lighting should be under the control of the party that it is to benefit most from its use and efficiency. Again, it can scarcely be denied that for street lighting, where population is scattered, arcs are preferable to gas lamps. Long lines of pipe, for the simple purpose of supplying street lamps, would not be necessary, wires being strung more cheaply than the pipe can be laid.

I do not think much of an argument presented to me yesterday, that gas companies generally take out their meters from premises wherein the electric light has been solely installed, unless paid rent for the use of said meters, and that this makes the consumer dependent upon the electric light at all times, thereby putting the electric lighting company to the expense of constant supply, and hence raising the cost "in the holder" of its light. I do not believe in taking meters out until the consumer orders them out, or until he becomes a radical opponent of the use of gas. The former is rarely the case, as there are few consumers who are willing to pin their entire faith to the supply of electric lighting from a central station, and the cheapest way to drive a customer to the other position mentioned, is, in my opinion, to take out his meter. Even where the consumer seems wedded to the electric light, it is better to leave in his way the constant temptation to use gas, and to throw in his way the constant suggestion that there are ends to which gas may be consumed, other than the one purpose of illumination.

It has been suggested also, since arrival here, that, after all, the most powerful reason why the gas companies should adopt the electric light is that it will tend to make them popular. The matter of popularity is a perilous one. From the greatest of stories down to the humblest of circumstances over which the public hold control, the change from the cry of hosanna is an easy one, and especially so is it the case in this country, where we have local reformers in every city, town and village, who are always seeking some Sindbad on whose neck to ride into temporary notoriety. I do not trust to popularity when, as has been the case within the past week, in my city, announcement of a reduction in the price of gas has been followed by the statement, in some of our largest dailies, that the meter wheels would now go round more rapidly than ever. While ignorance and vice go hand in hand, as they do in these cases, it is folly to dwell fondly upon the security of the bubble of popularity.

I am, too, more than ever convinced that popularity is but a bubble, since receiving the opinion of one of the best known members of the gas fraternity, a New York engineer whom all our associations delight to honor, and who is supposed to hold the good-will of the citizens and municipal authorities of his city by the most binding of ties. This gentleman stated to me at the Boston meeting, that the chief reason why his company would not adopt the electric light until it was compelled to, was that it would tend to depopularize the company, and that he considered it much better to have the electric light as an open opponent than to have the gas company furnish it, and thus raise the public cry of "monopoly." At the same time, the gentleman I have named did not consider that the right to cry "monopoly" was furnished when his efforts kept a franchise from being granted to a rival gas company that proposed to enter his city, put up an expensive and permanent plant, and furnish, under guarantee, a gas of higher candle-power than did the company of which he has charge.

If there is anything in the cry of monopoly to fear, it will disappear when the consumer of light finds, as he must and will, that with the supply of electric lighting in the hands of the gas company he will secure better and cheaper service than is or can be possible under the present dual systems. Deeply rooted in the heart of the gas consumer, more firmly than his inherent love of opposition to the powers that be, is his affection for his pocketbook, and the saving of the dollar is what will convince the consumer that the right course is being followed by a combination of the gas and electric interests.

I do not wish to be understood as endorsing the idea of better or cheaper illumination by means of the electric light. While this is generally admitted to be the case as concerned street lighting, I have never yet seen, nor do I soon expect to see, the electric light that for interior uses, will excel or seriously rival the Lungren burner. With the Wenham, to which our president flatteringly alluded in his address, this morning, I have little acquaintance, but am willing to accept his endorsement, which has no doubt been based on thorough examination and test. Nor do I ignore in favor of the electric light, the incandescent gas lamps that are now seeking the market. In at least two of these I have considerable faith, while the third is in hands that I feel will make a success of it. I do not ignore these weapons which the gas companies possess, or will possess, if a conflict of systems is finally to ensue. But I see clearly that the electric light is here and will stay here, as either for us or against us. Which is it to be? The consumer will demand the

Digitized by Google

electric light—is now demanding it. Shall the gas companies comply with his desires and give him what he wants, or shall we tell him to go elsewhere for it? It is a poor grocer who sells sugar and refuses to handle cut loaf, because he imagines that he can compel his customers to take granulated or go to the other corner. After a while they will go to the other corner too frequently for his enjoyment.

The question of fuel gas in connection with this subject of combined interests, is one of too much consequence to attempt to notice briefly; so we pass it by entirely, with the simple suggestion that the dovetailing of these interests, and the substantial aid which the introduction of the electric light by the gas companies will give to the further use of gas for fuel purposes, is well worthy of more consideration than it has as yet received.

The question then is a plain one: With the knowledge that electric lighting has come to stay (and we might add in a broader sense that electricity has come to stay), and that it is growing to be more and more a commercial element, is it wise for the gas companies to leave its use, for good or ill, in the hands of those who have no interests in common with us? Is it not better that we should take it into hand, as an acknowledged ally and friend? It may be said that the gas companies of one state in the country have determined the ethics of this matter for themselves, and their example is worthy of imitation. Shall it be followed?

"NO PATENT, NO PAY."

THE American patent system involves examination of specification, claims, and drawings, by trained examiners, which has forced up the standard of preparation necessary in patent cases, to a point that requires at least fairly good composition and execution, and has established a number of standards that necessitate careful and laborious work on the part of the person preparing and prosecuting an application, in order to thoroughly protect the invention involved. This results in making the soliciting of patents a most exacting and laborious profession, and one to which no first class man can afford to devote himself without fair remuneration.

Inventors may be divided into two general classes, one composed of men of intelligence, experience and practical capacity, whose inventions may be few in number as compared to the whole, but who really produce new and useful things and to whom the actual quality of their patent work is of the greatest possible importance. The other class is composed of persons, frequently from the rural districts, without either experience or information, who imagine that the less they know about any particular art, the more likely they are to strike something wonderful. Such inventions are as a rule beneath criticism, and the cupidity of this class of inventors in very many instances predominates over their common sense and judgment, to such an extent that they are always on the watch for some scheme that promises them the advantage.

Such plans are usually elaborated under the above heading, supported by arguments about as follows: "You will easily see that the solicitor who is willing to wager his fee upon the result of his judgment of the patentability of an invention will be more likely to secure you a patent than a person who demands pay for his services in advance." And this deceitful literature is disseminated throughout the entire country by the class of attorneys who do business under the plan of "no patent no pay."

If the patent office were responsible to inventors, and if it were the business of the examiners to ascertain *how much* an inventor was entitled to claim, and if they were required to point out to inventors the fact that they did not claim as much as they might, or wherein the scope and strength of their pending applications might be added to, or improved upon, then the "no patent, no pay" attorney, being the cheapest, would probably be the best, for that, if no other reason, and it would be arrant folly to throw away hundreds of dollars in the preparation of an important application when numbers of men could be found who were ready and willing to do work that would answer the purpose, for a much smaller sum.

But such is *not* the case, and the *patent office is responsible to nobody*. In the very nature of things its position is the exact opposite of that which is so frequently supposed. The business of the examiners is to present everything that can be opposed to the grant of an application; in other words, to show the state of an art, and call upon the inventor to amend his application so as to claim only what is left to him in view of the showing made. Being always on the opposite side, that is on the side of the public, they, the examiners, frequently decide that an inventor is entitled to less than he really is, and right here is where the services of a competent attorney are worth far more to the inventor of a really new and useful improvement than is generally at the time appreciated; for we have on one side an inventor ignorant of the technical requirements, and too often willing to concede almost anything to secure his patent, and on the other side an examiner thoroughly informed on that and similar points, and willing on behalf of the public, to see the inventor accept less than his due. It is between these opposing forces that the attorney works, and upon his judgment, care, and skill, the scope of the claims ultimately depends in nearly all cases.

Years ago it was thought that the laws providing for reissues allowed not only the correction of mistakes, but also the broadening of patents originally granted in too limited a form, but decisions upon a number of reissued patents so expanded have resulted in the now unquestioned establishment of the fact that a patent once accepted by the inventor, cannot, except under the most exceptional circumstances, be extended and broadened by reissue, thus practically throwing the entire responsibility upon the attorney. One reason why corporations so frequently appear to have the advantage over individuals is that they always employ the best available counsel and as a rule pay sufficiently well to make it worth while for a man to devote his time, energy and thought to their best interests, the result being that in contests with individuals they almost invariably win, as they should.

Business is business all the world over, and first-class men, properly qualified for the practice of their professions, do not work on speculation, from which we conclude that "no patent, no pay," is a snare and a delusion.—FRANKLAND JANNUS, in the *Patentee*, April, 1887.

SOMETHING ABOUT PATENTS AND PATENT LAW.

THE marked tendency of the United States Supreme Court, in many cases during the past few years, to check the grasping propensities of rich and influential corporations is certainly a hopeful omen. Not less gladsome is the well-attested fact that the Supreme Court has also, during this time, shown a most decided inclination to limit patent monopolies to the precise invention stated in the claims of the patent, as the statute requires should be done. The limit of extreme liberality in the construction of patent monopolies has been reached. The pendulum is now moving in the opposite direction. The golden mean is always to be preferred. But the problems of life seem to be solved only on the pendulum's principle of one extreme following another. About 22,000 patents alone were granted by the United States patent office during the last year. And there are now in force in the United States over 250,000 patent monopolies. But it is safe to say that nine-tenths of these patents are harmless—because no one will undertake the profitless task of infringing them. They are not worth infringing. Over $800,000 was paid out by inventors into the patent office last year as government fees for patents, designs, re-issues, trade marks and labels. The usual government charge for each patent is $35. But the inventors paid quite as much more to their patent agents or attorneys who did their patent office business for them. Indeed the patent attorney's charges are often much larger than the government fees for his services in piloting the inventor through the patent office. Sometimes the attorney's fee is $500, and occasionally several thousand dollars have been paid out in securing a single patent. And after the patent is procured, not rarely are large amounts of money and much time spent in making and vending the alleged invention, and generally without profit, but usually at a total loss. Men will make no investments in real property until the title has been carefully and thoroughly examined by honest and competent persons. But men will invest $50,000 or $100,000 in patent property without any examination whatever into the validity and commercial value of the patent. A competent patent lawyer can only give a reasonably probable opinion as to the soundness and validity of a patent, after a very careful study of the language of the patent in the light of the state of the art, as illustrated by foreign patents, printed books, public use, prior knowledge, etc. And a practical manufacturer and merchant can only judge of its probable commercial value aided by the patent lawyer as to precisely what the claims of the patent cover. It is true that most inventors fail to make use of all available sources to learn the state of the art before they make John Gilpin haste to take out their patents. When they get cooled off and have learned more of the state of the art they have discovered important improvements, and then they find that another patent must be taken out. All this is costly to the inventor, but profitable to the patent agent, who generally has an eye only to his fees as a patent attorney.

It is important for the purchaser of patents to bear in mind that the patented monopoly granted is only the invention described in the claims at the end of the specification, and not the invention described in the specification. In English patents, on the contrary, the precise invention patented must be gathered from the specification. And in English patents, also, it can never be known positively how broad or how narrow the patented monopoly is until the patent has been contested and passed upon by the courts of England. This is in sharp contrast with the precise character of a patent grant prescribed by the American law. In a United States patent, in order to constitute infringement, all the elements of the claim, or their substantial equivalent, must be used exactly as described in some one of the claims in order to constitute infringement under the patent law.

Then, again, the purchaser of patent, after he is fully

Digitized by Google

convinced that the claims of a United States patent appear to be valid in law, and not subject to any of the defenses named in the statute, yet he must further be convinced that the claims of the patent as granted are commercially valuable, and in order to arrive at a safe conclusion on this latter point a practical man well versed in the trade or business to which the invention belongs must give his best judgment as to whether there is any money or not in the sale of the article just as it is described in the claims.

Some risk, it will be observed, must in any event be generally taken in investing money in patent grants. But this risk would be reduced to the minimum if these precautions were taken before making the usually wild investment in patents, and consequently great losses would be saved. The proverbial uncertainty of the law is greatly intensified in patent suits; but this is not altogether necessary. Much, very much, could be truthfully said about unnecessary causes of this uncertainty in infringement suits. Certainly there is no good reason for it. But this discussion must be reserved for another occasion, because it would take so wide a range.

In conclusion, I cannot forbear quoting from a well-digested article on "Patent Law and Patent Practice," by the learned and accomplished editor of the *Central Law Journal*, St. Louis, Mo., of September 17, 1886:—

"One of the dark corners of the profession, to the average practitioner, is the patent law of the United States. The subject has long been turned over to specialists, and its practice so completely absorbed by them, that it is really no disparagement to even the best informed lawyers to say that they know very little about it. Nevertheless the subject is of such great interest to the people of the United States that the character, terms and operation of the existing statutes regulating patents, and especially their exposition and administration by the courts, are worthy of much more attention than they have ever received from the profession or the general public."—J. McC. PERKINS, in *The Age of Steel.*

ON REVERSIBLE LEAD BATTERIES AND THEIR USE FOR ELECTRIC LIGHTING.[1]

BY DESMOND G. FITZ-GERALD.

WHEN the cheap production of electrical power by means of the dynamo machine was first realized as a *fait accompli*, there were many who naturally, but somewhat rashly, assumed that cheap electrical power would immediately become generally available for electric lighting in private dwellings and for many other applications on a small scale. These anticipations, we all know, were doomed to disappointment—most of us have found it impracticable to introduce electrical power into the household; and the privilege of making use of the most beautiful, cleanly and hygienic means of artificial lighting has hitherto been denied to us. It may be interesting at the present moment—when the lead storage battery is claiming renewed attention—to glance briefly at the grounds for the sanguine anticipations which were formed soon after Werdermann brought the machine of Gramme into this country, to recall some of the main causes of their non-realization, to examine critically the accepted views as to the chemical and electro-chemical reactions involved in the working of storage or reversible lead batteries, to estimate the probable extent to which such batteries may be improved, or the room there may be for improvement, and, lastly, to consider, at least in its *prima facie* aspect, the question as to the practicability of carrying the original anticipations into effect by means of an improved form of reversible lead battery.

It is admitted by high engineering authority that, with steam engines of improved construction and of not less than 300 h. p. nominal, it is quite practicable to obtain a h. p. hour mechanical by the combustion of 2 lbs. avoirdupois of good coal. Allowing 20s. per ton for such coal, the cost of the fuel to develop this quantity of energy would be considerably under one farthing (.214d.). Putting the commercial efficiency of the dynamo machine at the very low figure of 70 per cent., the cost of the h. p. hour electrical would be less than one-third of a penny (.306d.). Taking everything into account, Sir W. Siemens in 1882, could not estimate the cost of production, in London, at a higher figure than nine-tenths of a penny (.895d.). He allowed 3½ lbs. of coal per h. p.; but I think, allowing for improvements, that that estimate may be diminished some 30 per cent. There are incandescence lamps that will yield a candle-power for every 2½ watts expended; and, taking the h. p. electrical as 736 watts, it would thus be equivalent to the illuminating power of 294 standard candles. The price, in London, of the gas to produce this illumination for one hour may be estimated at about 2½d.; and in London gas is cheaper than in most other localities. It was natural that figures analogous to these should arouse sanguine anticipations in the electrical engineer—

> And duller should we be than the fat weed
> That rots itself in ease on Lethe's wharf
> Were we not moved at this.

1. Read before the Society of Telegraph Engineers and Electricians, London, March 10, 1887.

But when, in this country and elsewhere, the requirements for domestic electric lighting came to be practically considered, it was found on the one hand that—in spite of the capabilities of the individual celebrated amongst our Parisian *confrères* as *le jardinier de M. Preece*—no private individual would, as a rule, willingly incur the prime outlay, trouble and comparative expense of a small steam or gas engine and a dynamo machine; and, on the other hand, that the cost and difficulty of laying down leads to supply even a populous district with electrical power from a central station was a very serious consideration. After 1882, when electric lighting was made a stalking-horse by the worst sort of company promoter, it was clearly seen that this mode of supply, involving an investment of capital even larger than that which had gradually been made in gas, would be out of the question for many years to come. I have no doubt that a system of distribution from a central station will ultimately be adopted to a large extent—but this will not be, I think, in the lifetime of those of us who have passed the middle-age; nor do I think that the distribution of electrical power from central stations will at any period altogether supersede the method of distribution, by means of elements in which electrical energy has been stored, to which I shall presently advert.

The electro-chemical means at present available for the storage of electrical energy cannot, either from a scientific or a practical point of view, be regarded as perfect; and it seems certain that they will be considerably improved in future years. The trite saying that the storage battery is still in its infancy is perhaps not inapplicable; but it would be a mistake to ignore the fact that important improvements have been made in this apparatus since (7 years ago) the cell of Gaston Planté was first modified by Camille Faure. Under the headings of "Storage Capacity" and "Weight per Horse-power hour," I have jotted down principally from my note-book, in tabular form, some figures, subject to correction and amplification, which in some measure illustrate this improvement, although there are other points of equal importance which require to be taken into account. The "lithanode" mentioned in these tables was the subject of a paper which I read at the British Association Meeting at Birmingham, and which will be found in the *Electrical Review* of September 17th, last year. It is peroxide of lead (with more or less sulphate of the metal) in a coherent and highly-conductive form, having generally a specific gravity between 7.5 and 7.9. I shall have occasion again to refer to this material presently. There are specimens on the table.

TABLE I.

STORAGE CAPACITY OF VARIOUS SECONDARY CELLS.

Name of cell.	Per lb. of Pb.		Per kilo of Pb.		Authority
	Foot lbs.	Watt hours.	Kilogram-meters.	Watt hours.	
Planté	12,000	4.52	3,654	10	
Faure	18,000	6.78	5,435	15

In table i., I have taken the liberty of placing a note of interrogation after the values, relating to the storage capacity of the plates formerly manufactured by the Electrical Power Storage Co., taken from the paper read by my friend and old pupil, Mr. F. G. Howard, in June, 1885, at a meeting of students at the

Digitized by Google

Institute of Civil Engineers. No doubt Mr. Howard referred to the total storage capacity, instead of the useful capacity, of these plates; but even in this case the value given would seem to be much too high. Certainly the plates now issued by the Electrical Power Storage Co. are at least equal to those manufactured by them two years ago; and at the present moment the useful storage capacity claimed by them per pound of battery is, I believe, three ampere-hours on a rough average. In the smaller cells this value may be surpassed—in the larger it is scarcely attained. The present "thin-plate" Electrical Power Storage cells have a capacity of 2.8 ampere-hours per pound of battery. In practice, as for instance at the Colonial and Indian exhibition, this value, we know, is not always even approached. Now, taking the high value comparatively of three ampere-hours per pound of battery, the horse-power hour cell would weigh 129 pounds. But according to the values I have called into question, 41 pounds of lead in the battery would suffice to produce the horse-power hour; and this lead would constitute only one-third of the total weight of the battery—a ratio which is far too small, and requires to be increased to at least one-half, which is the *reductio ad absurdum* of the high figures put forward by Mr. F. G. Howard.

A high ratio of stored energy to weight is not always the most important consideration in a reversible lead battery; and the few data I have collected in tabular form would have been of greater interest if I had specified in each case the *rate of discharge*, since it is well known that the useful capacity becomes diminished as this value is increased. I will to some extent remedy the omission by stating, in regard to the lithanode battery, that when the rate of discharge is about .446 ampere per pound of plates, or .257 ampere per pound of battery, the useful capacity may be as high as 9.32 ampere hours per pound of plates, or 5.3 ampere hours per pound of battery. But, when the rate of discharge reaches .64 ampere per pound of plates, or .36 ampere per pound of battery, then the useful capacity falls to 8.6 ampere hours per pound of plates, or 4.8 ampere hours per pound of battery. These figures do not by any means represent the recent results obtained by the Union company. I have just been informed, however, that the figures I have given are not considered applicable to the "Union" cell, and that the results obtained in recent experiments are expressed by the following table.

UNION CELL.

Rate of discharge.		Capacity.	
Amperes per lb. of		Ampere hours per lb.	
Plate.	Cell.	Plate.	Cell.
.68	.41	9.2	5.5
.88	.53	7.1	4.3
1.2	.72	6.2	3.7
1.5	.9	5.5	3.3

Whatever may be said of the lead storage battery itself, it is quite certain, I think, that our electro-chemical knowledge in relation to it is "in its infancy." We should be thankful even for small mercies in this direction, for very few electricians or electro-chemists have given any real attention to the matter, which is one of vital importance to progress. Bnt we should be specially grateful to Dr. J. H. Gladstone and to the late Mr. Alfred Tribe, who gave a great deal of careful labor to "The Chemistry of the Secondary Batteries of Planté and Faure."[1] I am glad to say this before criticising, to the best of my ability, some of their conclusions from which I venture to differ—or to imagine that I differ.

In the first place there is a little matter—possibly a *lapsus*—of no great importance perhaps in itself, but which seems to me of importance by reason of the detestation in which I hold anything in the form of "white sulphate"—non-conducting sulphate—in the negative element of a lead storage cell. "White sulphate" is the only thing I will not forgive in a battery, and I often deprecate the maker of an element containing such an article. In their little work under the above mentioned title, Messrs. Gladstone and Tribe propound the following question and answer: "In a Planté or Faure battery, the mass of peroxide which is in contact with the (negative) metallic lead plate expends its energy slowly. How comes it to pass that if the same mass of peroxide be brought into connection, through the first lead plate. with another lead plate at a distance (in the same electrolyte) it expends its energy, through the greater length of sulphuric acid, in a tenth or a hundredth part of the time? The answer . . . . is doubtless to be found in the formation of the insoluble sulphate of lead, which clogs up the interstices of the peroxide, and, after a while, forms an almost impermeable coating of high resistance between it and the first metallic plate." Now it appears to me that this suggested explanation involves a misconception as to the conditions which are favorable to the passage of the local current, of which the direction is from the metallic support to the peroxide through the electrolyte and from the peroxide to the metallic support by simple conductive contact. Not that the resistance (electrolytic) between the supporting plate and its peroxide is *common* both to the local circuit and to the main circuit; for there must be a simple conductive contact between the plate and the peroxide at one or more points (otherwise the detached layer of peroxide would become inactive, and there would be no current in either circuit), and the main current would pass wholly through this contact—as indeed would the local current in its passage from the peroxide to the support. But it is evident that the local current, under the given electromotive force, will be inversely as the sum of the resistances in its circuit, and that one of these resistances—that which opposes its passage from the peroxide to the support—must be small (since otherwise the main current would be impeded). The remaining resistance in the local circuit—that which opposes the passage of the local current from the lead support to the peroxide *through the electrolyte*—must evidently be very considerable in order to comply with the conditions under which the current in the main circuit may be ten or a hundred times greater than that in the local circuit. In my view, the electrolytic resistance in the local circuit would be diminished instead of augmented, by interposing even an almost impermeable (but more or less moist) coating of sulphate of lead between the peroxide and its support, excepting at one or more points where the peroxide and the lead would be in perfect contact. To maintain perfect uubroken contact everywhere between the layer of peroxide and the lead supporting plate, would, I thing, be the best means of diminishing local action by augmenting the electrolytic resistance in the local circuit. And this, in substance was the burden of the paper read by Messrs. Drake and Gorham at the British Association last year.[2] The clogging up of the *interstices* in the peroxide might, I am ready to admit, be beneficial, provided this unbroken contact were maintained. It may be observed, however, that the suggested explanation appears to be further disproved by the figures given by the authors of the work referred to. During the first two hours, when the quantity of sulphate formed is a minimum, the quantity of peroxide reduced by local action is only 3.6 per cent. per hour. In the next hour, when the quantity of sulphate must have augmented, the percentage of peroxide reduced is shown to be nearly 8; and in the following hour it rises to about 10.

Passing to a matter of more general importance, the equation given by the writers I have named as applicable to the batteries of Planté and of Faure—and presumably also to all lead secondary batteries with the same electrolyte—is substantially as follows:—

$$PbO_2 + 2H_2SO_4 + Pb = \underbrace{PbO + H_2SO_4} + PbSO_4 + H_2O.$$

The compounds bracketed together react, however, upon each other, so that the final result may be expressed by

$$PbO_2 + 2H_2SO_4 + Pb = 2PbSO_4 + 2H_2O;$$

the final result being sulphate of lead on both plates.

This equation is very simple, and has been generally accepted as entirely satisfactory. As an expression merely of the chemical results observed, after a certain percentage of the peroxide has become reduced, it is perhaps unassailable. As an electro-chemical equation, applicable during the whole period of the discharge of a lead secondary battery with the given electrolyte, it is impossible, I think, to accept it. It is not the old fallacy—recently protested against by Mr. Swinburne, and which is to be found in this equation—of supposing that water, and not an acid or a salt, is the electrolyte in the voltaic battery, that I have now to dwell upon. I will endeavor to lay before you the other difficulties I have found in the way of its acceptance.

But in the first place it will be expedient to consider whether there has been any intention of putting forward or accepting the above formula as an electro-chemical equation, expressing the reactions on which the efficiency of the battery is dependent. Has there actually been any assumption that the whole of the peroxide is, or may be, converted into sulphate of lead? that a large proportion of isolated sulphate of lead—"white sulphate"—is necessarily produced in discharging the battery? that the reduction of the peroxide takes place, not in two or more stages, but continuously? and that the electromotive force of the battery is independent of the quantity of sulphate which has been produced from the peroxide? Because, if not, I might be setting up imaginary antagonists and incurring unnecessary trouble in endeavoring to overcome them.

The authors of the work already referred to make use of the expression given above: "The final result being sulphate of lead in both plates." Dr. Gladstone, moreover, has explained that, "When we stated that sulphate of lead is finally the only product of the discharge, we were referring to the disappearance of any peroxide, and did not mean to imply that in actual practice the whole of the spongy lead is usually converted into sulphate." Mr. Tribe, in *The Electrician* of July 10, 1885, wrote that "One of the conclusions was that both the peroxide of the negative

1. Their work, under this title, is published by Macmillan.

2. "On the Treatment of Secondary Batteries." See ELECTRICIAN AND ELECTRICAL ENGINEER, vol. v., p. 418.

Digitized by Google

plate and the finely-divided lead of the positive were converted into lead sulphate during discharge." Mr. George F. Barker, in his paper read at the Montreal meeting of the American Association for the Advancement of Science, says: "My experiments with the Faure battery confirm entirely those of Gladstone and Tribe as to the formation of lead sulphate." "On examining the plates, lead sulphate formed the entire coating upon both of them." Mr. C. T. Kingzett states that "As fast as the monoxide of lead, produced by reduction at the negative pole during discharge, forms, it is converted into sulphate. Upon complete discharge then there remains two supports of lead coated with sulphate of lead." And Prof. Oliver Lodge says: "The use of peroxide alone (without any support of lead) looks hopeful; but, when the cell is discharged and the peroxide reduced, the plate will no longer be a conductor—and it does not appear probable that such a cell could ever be charged up again." This conclusion, I may here state, is most emphatically disproved by the "lithanode" battery plates now before you, most of which have been charged and discharged—down to the potential of 1.8 volt—a great number of times, without losing their conductivity or exhibiting the smallest patch of "white sulphate." [Samples of exhausted plates were handed round.]

Mr. G. F. Barker further observes that, "Obviously, so long as any peroxide is present, the electromotive force is constant." The same experimenter also makes the following very suggestive note, showing that one at least of his cells had been, apparently accidentally, worked upon an improved system. He says: "In one of my Planté cells, the peroxide is beautifully crystalline and very hard. Not a trace of (free) sulphate has been formed in it, apparently, though it has been in use for six months, and has been frequently charged and discharged during that time."

On the other hand, Messrs, Gladstone and Tribe state (*loc. cit.* p. 32), in relation to the negative plate:—"At the conclusion of the action, we have always found more or less of the substance unaltered. Thus, as one instance, after a discharge lasting five days, and approximately complete, we found that only 68 per cent. of the deposit was lead sulphate." And Mr. J. Swinburne (in *The Electrician* of July 10, 1885) makes an important observation in the same direction. He says: "The appearance of the coating of an ordinary discharged peroxide plate does not prove the absence of sulphate, for only a very small proportion can be sulphate. Some years ago, when I made a large number of experiments on batteries, I found that in no case more than six or seven per cent, of the coating is used, even when the cell is completely run down. The expansion of the peroxide of lead in becoming sulphate perhaps blocks the coating up."

Let me at once observe that if Mr. Barker were right in stating that the E. M. F. is constant so long as any peroxide is present I should have less difficulty in accepting the above-mentioned formula as the electro-chemical equation applicable to lead secondary batteries. But, like Mr. Swinburne, I have found that long before the whole of the peroxide is exhausted the E.M.F. has fallen practically to zero. If the formula be true, as the electro-chemical equation of the battery, why should there be any fall in the electromotive force before the peroxide is exhausted? Is it because the peroxide becomes "blocked up" or clogged, or so diluted by the inert material, that the support or contact piece becomes rapidly "polarized" by hydrogen? If so, the formula may be true. But on open circuit, when there can be no polarization, and with a strip of solid peroxide without support, we should, if the formula be true, obtain the full E.M.F. corresponding to the nature of the chemical reaction indicated by it. We should expect this so long as any peroxide remained—certainly when only 25 per cent. of the quantity originally present had been consumed.

(*To be continued.*)

CORRESPONDENCE.

NEW YORK AND VICINITY.

Moving Day and its Changes.—Property Owners Object to a Handsome Pole Line.—Various Companies after the City Lighting.—Improvements in Police Alarm Systems.—Electric Railways in New Jersey.—Liberty's Torch Visible 23 Miles.—Telephone Poles Removed by the East Orange, N. J., Authorities.

OUR annual moving day brings perhaps more tribulation to electrical people than any other portion of the community. Extensive preparations are made by the quotation, district, telephone and electric lighting companies for numerous changes by their subscribers, while in many cases their own moving must also be provided for. Probably the largest undertaking of this kind is the transfer of the down-town telephone exchanges to the new building now approaching completion at 18 Cortlandt street, which has been erected since last May by the Metropolitan Telephone and Telegraph Co. The work of consolidating the exchanges would have proceeded with no embarrassment had proper underground facilities been provided by the subway company.

The Baltimore and Ohio Telegraph Co. is also making an important change, by moving its main operating room and official headquarters from No. 63 to No. 415 Broadway, corner of Canal street, where the old Brandreth House is being thoroughly refitted for general occupation by the railroad, express, and telegraph departments of the Baltimore and Ohio Telegraph Co. In order to have the work permanently done, it was originally proposed to bring the wires to the new quarters underground, but no conduits having been provided under the direction of the subway commission, rights of way and permits were secured for the privilege of placing the cables on poles. Three kerite and one bitite cables of 50 conductors each, are used in connecting the new quarters with the old cupola at 63 Broadway. The new operating room occupying the entire top floor, is very neatly fitted up with quartette tables and a handsome switch-board. Every precaution has been taken to provide for the thorough working of this extensive telegraph system, all of the inside wiring of the building being substantially done with Kerite insulated wire. The building although narrow, is not hemmed in by adjacent walls, ample light and air being secured through the windows fronting on Broadway, Lispenard, and Canal streets.

The Commercial Cable Co. removes its offices from the historic telegraph corner at 21 Wall street, to the opposite corner, in the basement of the Drexel building, near the location of the Pacific and Atlantic office 17 years ago.

The property owners on West 73d street are making strenuous efforts to prevent the completion of a new pole line to Yonkers, basing their objection to it on the plea that the poles and wires are a nuisance, and had been officially declared so by the legislature when it created the subway commission.

Since the organization of the East River Electric Light Co., which proposes to take a hand in the city lighting if it can get a chance, other electric lighting companies have come forward to secure a share of the work. The Brush and United States companies have worked in harmony, and their old price for lighting was 70 cents per night, which they have reduced to 65 cents this year. The contract was not awarded to them however, as a movement was on foot to permit new companies to enter the field. The Waterhouse Electric Manufacturing Co., of Hartford, and the American Electric Manufacturing Co., of New York, have both applied to the board of aldermen for permission to erect poles and string wires in all the streets and avenues of the city, and furnish the city with one public light free, for each 50 private lights paid for by subscribers. The applications were referred to the law committee, and will probably be sat upon at the proper time.

Five police alarm systems are being tried in the Twenty-ninth precinct. As yet only one system has been used. It is a small square box attached to a lamp post or telegraph pole on each beat, containing an automatic telegraph instrument which communicates with the station house and hospitals. When an ambulance is required the policeman touches his hospital alarm and communicates directly with the hospital authorities. The old system required the policeman first to go or send to the station, whence the sergeant telegraphed to the central office. Another system, which is used in the city of Chicago, will be tried in a few days. Little booths, just large enough for a policeman, will be erected on the street corners. A booth will contain an electric signal and a telephone. The policeman can stand at his post and communicate with the station by telegraph and telephone. A little instrument in the station house registers his wants on a slip of paper. One of these booths is at Eighteenth street and Seventh avenue now. Three other systems will be tried. The Brewer system, which has not yet been in practical use, will cause a red light to bob up and down around the glass of a street lamp when a policeman on that post is wanted from the station house. If he is several blocks away this little light will attract his attention. An automatic alarm box is attached to the lamp post, by which he can communicate with the station. The system used in New Haven will also be exhibited. It is virtually on the same principle as that used in Chicago, except that no booths are used. It is simply a box large enough to contain a telephone and telegraph instrument, which can be placed conveniently against a house or on a telegraph pole.

The experimental section of an electric railway at Orange, N. J., has now been in operation sufficiently long for the open mouthed natives to satisfy themselves that a car can be moved without horses. Electric railway schemes are also cropping out in other parts of the conservative state, Asbury Park and New Brunswick being the latest converts to the innovation.

It has been officially announced by the pilot commissioners that the light on the Statue of Liberty is visible on a clear night at a distance of 23 miles.

The war over the telephone poles in East Orange, N. J., has terminated for the present by the township authorities, the road overseer with a gang of men having removed the poles on Park avenue. The demolition of the line was witnessed by employés of the New York and New Jersey Telephone Co., who announced that legal proceedings against the township would be commenced by the company.

NEW YORK, April 25th, 1887.

PHILADELPHIA.

Councils and Electric Franchises.—City Underground Wires.—A New Telephone Co.—The Philadelphia Telegraphers' and Electrical Association.—Death of Mr. George H. Grace.—Proposed State Legislation on Underground Conductors.—Railroad Brake Tests in May.

THE first meeting of the new board of highway supervisors was held on the afternoon of April 14th. After chief Walker had been granted permission to extend the city's underground wires, the applications of the underground electric companies were considered. There were many corporations seeking privileges, which, in their entirety, would occupy nearly every main street in the city. Director Wagner looked up the laws and ordinances, and found that only one company had entirely complied with the requirements laid down. This was the Penn Electric Light Company, which was granted permits to put down conduits on South street from 8th to 25th, and on Chestnut street from 2d to 23d. After the permit had been granted for Chestnut street, chief Ogden remarked that it would be the last conduit which can be placed under the street. The requests of the Morse, Edison and Keystone companies were postponed.

The work of laying the underground electric light wires on the west side of Broad street from Columbia avenue to Fairmount avenue, which has been in progress for two weeks past under the supervision of chief Walker, of the electrical department, has been completed, and the lamps will be lighted for the first time this evening (April 15th). The conduits are 4,700 feet long and contain 4,800 feet of cable, which connect with 15 lights erected on poles. The lamps are 22 feet above the pavement.

Articles incorporating the New Jersey Telephone Company were filed at Woodbury yesterday (April 14th). The capital is $250,000, and the 7 counties south of Trenton will be the field of the company. The officers are: C. W. Starr, president; H. C. Loudenslager, secretary; W. H. Livermore, treasurer; M. W. Newton, J. E. Highley, G. H. P. Barber, Joseph B. Roe, J. M. Henderson and T. Earl Budd, directors.

The difficulties between Jesse W. Starr, Jr., of Philadelphia, who contracted to furnish Belvidere, N. J., with electric light, and his creditors, were to-day adjusted. He pays the labor claims in full and gives security for the material furnished in construction, and the creditors have withdrawn their suits. The sheriff seized the property three months ago, on the night of the first trial, and has since held it under writs of attachment. He released it the latter part of last month. The Belvidere Electric Lighting Company will complete the contract, and the town will be lighted by electricity within a short time.

A number of gentlemen effected a permanent organization on March 19th, under the title of the "Philadelphia Telegraphers' and Electrical Association." The object of the association is to encourage a fraternal feeling, and promote self-improvement in electrical science and other kindred subjects. The membership will be composed of persons engaged in the telegraph, telephone, electric light and other electrical pursuits, including manufacturers of supplies. This is a much better method for the operators to improve their condition than to organize secret societies for "striking" purposes.

Mr. George H. Grace, superintendent of telegraph lines on the New Jersey Central Railroad and its branches, died at Easton on April 13th. It is rumored that Mr. James L. Mingle, of the W. U. Co., of this city, will succeed him.

Senate bill No. 254, providing for the incorporation, regulation and protection of companies for the construction, maintenance and operation of electrical subways and underground conduits, which has already passed the Pennsylvania Senate and is now before a House committee at Harrisburg, is of special importance to Philadelphia in its present effort to secure well paved and well cleaned streets. It provides that such corporations shall be authorized to construct subways and underground conduits for carrying electric wires and conductors of all kinds under, along and through any of the public streets, lanes, alleys, roads and highways, and under and across any of the waters and streams in any county, city, town, borough or district of the state mentioned in the charter of such corporation, and to enter upon and open at any time any street, lane or alley, either for the purpose of construction or repair. The companies are to do as little damage as possible to the streets and not obstruct their free use where it can be avoided, and they are to be subject to such reasonable regulations as the councils of cities or boroughs may adopt in regard to grades and the convenience of the public. Provision is also made for the rental of the underground wires; also penalties for interfering with the property of the corporations. The bill is the subject of the severest criticism by officials of the city, in that it places the opening of the streets entirely beyond the regulation of any authority except the corporations who wish to use them.

In speaking of these provisions of the bill, David R. Walker, chief of the electrical department, characterized it as an infamous measure. "Under it," said he, "corporations are allowed to do just as they please. It gives them the right of eminent domain. They can construct a subway 10 feet wide or 2 inches wide, as they choose. They can break up our streets. They are not bound under the bill to do the work under the supervision of any city official whatever, and councils have no voice as to how the work shall be done. It is a case of go-as-you-please. There is nothing that compels them to restore the streets or arrange them as they were before being opened. They can tear up any kind of pavement, patent or improved, if they desire to do so, for there is no restriction. If the legislature should pass the bill requiring legislation from councils under rules and regulations that councils might enact it would be a different matter altogether. Under the present system of constructing subways or conduits the city reserves the right to use one or two ducts, and the companies are bound to furnish the city a number of wires, this being the only consideration to the city for the use of the streets. By means of this we are enabled to put the police and fire service underground without any great expense. For this reason the present system is worth hundreds of thousands of dollars to the city. The bill now before the legislature would do away with these privileges altogether. The city could not keep any of the wires without paying the price the companies choose to ask."

An extended test of various kinds of railroad brakes will be made at Chicago in May next under the auspices of the Chicago, Burlington and Quincy Railroad. There will be but one system of buffer brakes exhibited, but Card, Carpenter, Eames, Park and Westinghouse, all well-known patentees, will exhibit systems wherein compressed air or vacuum furnishes the force for braking, but a simultaneous application is secured by electricity. The latter is a desideratum long sought for, and is especially desirable in cases of braking freight trains. H. D. Garrett, master mechanic of the Pennsylvania railroad at the West Philadelphia shops of that road, says his company is at present much interested in a series of experiments with brakes in which electricity plays an important part. These experiments are being made at Altoona, and the results have not been made public as yet.

PHILADELPHIA, April 16, 1887.

BOSTON.

Annual Meeting and Election of the American Bell Telephone. The Government Telephone Suit.—Output of Telephones by the Bell Co.—Discussion of Car Lighting at the New England Railroad Club.—Business of the Electric Accumulator Co. in Boston.—An Exclusive Electric Light Franchise Refused by the City of Dover, N. H.—Perils of Electricity.—Burial of Mr. Robert S. Boyd.—The Late Daniel Davis.

THE annual meeting of the American Bell Telephone company was held 29th ult.—President W. H. Forbes in the chair.

Mr. Charles Eustis Hubbard was chosen clerk of corporation, Mr. William R. Driver, treasurer, and the following named directors were also elected: Francis Blake, Charles P. Bowditch, George L. Bradley, Channing Clapp, Alex. Cochrane, William H. Forbes, Charles Eustis Hubbard, Gardiner G. Hubbard, John E. Hudson, Robert B. Minturn, Charles E. Perkins, Thomas Sanders.

An opinion has just been filed, April 4th, by Judge Colt, in the United States circuit court, in the case of the United States *vs.* American Bell Telephone Co., denying defendant's motion for leave to plead certain facts, in addition to filing a general demurrer to the bill. The judge says that to grant this motion would be contrary to the regular and orderly course of pleading in equity cases, as it has been decided that there is no equity rule which allows a defendant to demur to the whole bill, plead to the whole bill and answer to the whole bill at the same time, and that the effect of such pleading is, that the plea is taken as waiving the demurrer, and the answer as waiving the plea. Upon the ground urged by defendant that it is within the discretion of the court to grant such a motion, and that the court has power to mould its rules in relation to the time and manner of answering, the judge says that this power should not be exercised unless for good and sufficient reasons and to prevent injustice. The defendant has asked leave to plead, in addition to filing a demurrer, that the bill refers to litigation previously had with reference to the scope and validity of the patents in controversy, but that it does not state the result of such litigation or the decisions therein, or that the questions of fact or law sought to be raised by this bill have been argued before the supreme court in suits for infringement of these patents, and are now held under advisement by that court, and that, therefore, defendant's proper course is to plead the same, and for this reason it asks leave of the court to plead the determinations affecting the validity and scope of the patents. It also asks leave to present by plea copies of certain letters from the commissioner of patents to Elisha Gray, the contents of which the bill purports to state, and it further represents that it would be unjust to require the expensive litigation already had to be repeated, and that it would be indecorous to re-try any questions pending before the supreme court until that court shall have pronounced its judgment. The judge says upon these points that, so far as the plea proposes to set up prior litigation respecting these patents, no bar or estoppel is shown such as would constitute a good plea, because it does not appear that

Digitized by Google

the parties or the subject-matter are the same, and that no sufficient justification for granting this motion is shown thereby. He concludes by saying, "In a cause of this magnitude it seems to me the ends of justice are more likely to be reached by following the regular and orderly procedure of courts of equity, and that the court should hesitate, unless from grave considerations, to depart therefrom."

Our legislature continue to make adverse reports on telephone and telegraph legislation, on the various matters brought before them—such as placing corporations doing such business under the control of the railroad commissioners; prohibiting them from holding stock in other companies; regulating their conduct and rates, etc.

The output of telephones by the American Bell company for the month ending March 20th, and the first three months of the current year, is herewith tabulated:

March—	1887.	1886.	Increase.
Gross output	4,372	2,819	1,553
Returned	1,452	1,232	220
Net output	2,920	1,587	1,333
December 21 to March 21—	1886-7.	1885-6.	Increase.
Gross output	11,751	8,822	2,929
Returned	5,326	4,188	1,138
Net output	6,425	4,634	1,791

Comparison with previous month—

	March.	Feb.	Jan.	Dec.	Nov.	Oct.
Gross	4,372	3,405	3,974	3,946	3,340	3,259
Returned	1,452	1,918	1,956	1,686	1,825	1,745
Net	2,920	1,487	2,018	2,260	1,515	1,514

The New England Railroad Club on the evening of the 13th, held its regular monthly meeting at its rooms in the passenger station of the Boston and Albany railroad, the topic for discussion being the lighting of railroad passenger cars. There was a large attendance of members and other gentlemen interesed in the subject. In one corner of the room there was a practical demonstration of the Pintch light, two of the lamps having been erected. Ex-Gov. Howard, of Rhode Island, representing the Pintch company, explained that system of gas lighting at some length. He said the actual cost is about $12 per car per year, exclusive of cost of fitting up the cars and the plant for furnishing. Including those items, the cost is not over $40 per car per year. He expressed his belief that where there is a 300° test required of oil used in cars, there is not a railroad but violates the law. Mr. Adams and Mr. Curtis both took exception to the latter statement, claiming that frequent tests made by the state inspector demonstrated that the oils were up to the test. Mr. Coney explained that he had had large experience in manufacturing kerosene, and he very much doubted if the oil used would stand the 300° test when made by the best instruments. He declared he did not believe any accident ever occurred with oil having a fire test of 150°. President Lauder said he hoped the railroads and the public would not lose their heads because of recent accidents. He thought the present system was a good one, and plenty of light can be obtained, if enough lamps are put in, though the more lamps put in the more heat is generated. He knew of no instance where cars had been set on fire by the lamps, as a very slight shock invariably puts the light out. He thought the heavy expense of lighting with electricity would prevent its general use at present. Gen. Elbert Wheeler, treasurer of the Wheeler Reflector Co., stated that, with proper reflectors, he could give the same amount of light with 12 electric lamps as is given by the 20 in the Boston and Albany cars. Mr. Marden of the Fitchburg railroad said that he had put in one car five lamps with the Acme burner, and he believed that the car is the best lighted of any running out of Boston, with, perhaps the exception of the Albany's electric lighted cars. He believed, however, in electric lights, and is fitting up a car which is to be lighted by storage batteries furnished by the Electrical Accumulator Co. Outside of the work being done by him, the entire expense of fitting up the car including the accumulators, is only $375. He is putting in 12 lamps.

The Electrical Accumulator Co., of New York, are represented here by Mr. John T. Moriarty, at 19 Pearl street, the old offices of the Domestic Electric Co. They are well under way, putting their batteries into use in connection with electric light installations, etc., having facilities for charging their batteries here. A storage battery plant for electric lighting has been put into the new Massachusetts Hospital Life Insurance Building on State street, by Mr. Moriarty, and is giving good satisfaction. The noise and jar of running engines and dynamos during office hours is entirely obviated; the steadiness of the incandescent lights is very noticeable.

The police signal system continues to agitate the residents of our town. There seems to be an opinion that the present municipal government is opposed to such aids to the police system.

At Dover, N. H., the board of aldermen, on the 25th ult, refused to grant the petition of the Thomson-Houston Electric Light Co. for a franchise to erect and maintain an electric light plant in their city, exclusively, for five years. A correspondent of one of our daily papers, writes to warn people of the evils to come, when the electric motor will infest our streets. I quote one of the evils:

"This is the danger to watches in the pockets of passengers who may come within the influence of the dynamos used upon the cars.

The magnetic field of dynamos covers a distance variously estimated at from 10 to 30 feet, or perhaps even more, within which distance any watch would be liable to become magnetized, and thereby rendered, if not entirely useless, at least very unreliable until demagnetized—a process which, even if perfectly successful, is expensive, and a very undesirable necessity to incur.

The public is even now liable to the same accident from electric light machines, some of which are situated in the basements of buildings, and a watch in the pocket of a person standing in a store over such a machine might easily collect and retain sufficient magnetism to destroy its time-keeping qualities.

Many of the perplexing variations of watches are, without doubt, occasioned by magnetic currents induced by causes not always easily explained, but which are probably due to personal temperament, or physical electricity; and many watches are found to have become magnetized from being in the vicinity of magnets and dynamos, as well as from the effects of lightning.

Even though a watch has not itself become magnetic, its motions will be disturbed by any articles of steel which may have become so, carried about the person; and cases have been known where this trouble has been caused by the *steel springs of corsets*, or by some of the magnetic or galvanic appliances frequently worn."

Perils may indeed attend too close proximity to the source of danger italicised in the last paragraph.

Mr. Robert Southgate Boyd, special agent for the American Bell Telephone Co., who lost his life at the terrible fire at the Richmond hotel, Buffalo, was buried on the 6th inst. The funeral services were held in Cambridge, Mass., the residence of Mrs. Boyd. A delegation of gentlemen from the office of the American Bell Telephone Co., attended the services. It is pleasant to chronicle the fact that the Bell company proved itself to be a corporation *with* a soul. Under the direction of the general manager, Mr. Hudson, two special agents, Messrs. Hovey and Doolittle, were sent to Buffalo, to find out the facts, of the case, and to recover the body of Mr. Boyd. No effort was spared by the management and the gentlemen named, the result being the discovery of the remains, a bunch of keys and a part of the frame of a traveling bag, belonging to Mr. Boyd, near the body. No words of mine can add to the estimation in which Mr. Boyd was held by those who knew him.

The following justly appreciative notice of the death of Mr. Daniel Davis appeared in the daily press, contributed by T. H. "Daniel Davis, died at Princeton, Mass., Tuesday, March 22d, at the age of 74. Probably no man in this country had such a thorough knowledge of electricity 40 years ago as Mr. Davis. Born in Princeton, of a mechanical family, he worked on his father's farm until he was 21, and came to Boston in 1833. His first work in this city was pumping soda for Mr. Darling, who then had a large soda factory in Franklin avenue. Being greatly interested in electrical experiments, he soon became acquainted with Dr. William King, who had a shop on Cornhill, manufacturing static electrical machines and also constructing and putting up lightning rods. Mr. Davis soon found employment with him. His first job was constructing and putting up the rod on the court house in Boston. This was made of flat copper ribbon, and is now in as good order as when first placed in position. He also constructed and put up the rods on the buildings in the Charlestown, Navy Yard. In 1835 he began business for himself at No. 11 Cornhill, in partnership with the late John Temple, under the firm name of Davis & Temple. In 1837 Mr. Davis bought out the interest of his partner, and commenced the manufacture of electro-magnetic apparatus. At that early day there was little practical use for electricity, and his principal business was manufacturing and constructing apparatus to illustrate the general principles of voltaic and dynamic electricity. In connection with the late Dr. Charles G. Page, he engaged in many electrical experiments, their joint efforts resulting in discoveries now used in many applications of electricity to practical purposes. They continued their experiments together until the fall of 1839, when Dr. Page accepted a position in Washington as examiner of electric patents. Mr. Davis's business increased very rapidly, he being the only man in the United States at this time who made electro-magnetic apparatus In 1842 he published "Davis's Manual of Magnetism," this being the first work published on that subject in the world. It was used as a text-book in all the principal scientific institutions in this country and England. He was a man who did not believe in patents. Had he patented some of his inventions he would have died a millionaire. He invented the art of electrotyping in copper wood cuts and type such as are used to-day, and gave his invention to the world. In 1846 he electrotyped in copper the arm of a child, which has been lately claimed as a new invention. This arm is still in existence. In 1840 Prof. Gareaux, of Paris, arrived in Boston with the invention of Daguerre. Mr. Davis made a set of apparatus and probably took the first daguerrotype taken in this country. Elias Howe, the famous sewing machine inventor, worked for him and made his first machine in his shop. Mr. Davis was also the first man in this country who did electro gold and silver plating, and taught the art. In 1844 Prof. Morse had just introduced his telegraph, but it was a very rude and impracticable machine, and it was put into Mr. Davis's hands for improvement and he put it in its present state. He received several gold medals from various exhibitions for his inventions and skill as a manufacturer. His

Digitized by Google

shop was the headquarters for professors, scientists and electricians for many years. The writer has seen Dr. Hare, Professors Webster, Hitchcock, Silliman, Henry Abbott, Farmer and Channing, and most of the scientific men of the time in his store. Mr. Davis would be in his shirt sleeves trying some new experiment, with the professors crowding around him as much interested in his work as himself. In 1852 he retired to his farm in Princeton, where he passed the remainder of his days in agricultural pursuits. He was a kind-hearted man, and the soul of honor and integrity."

BOSTON, April 16th, 1887.

CHICAGO.

Failure of Council to Pass the Electric Light Appropriation.—The Buffalo Hotel Fire: The Late Robert S. Boyd.—The Edison Light Co. Secure a Franchise in Chicago.—A Patent Right Raid on City Fire Departments.—Mr. W. H. Johnson Located in Chicago.—Proposed Consolidation of Electric Light Interests.—A New Electrical Firm.

THE electrical people, as well as the community in general, have been quite encouraged for some months back, by the belief that a proposition before the council leading to lighting the inland waterways of our city by electricity would be acted upon, and the appropriation ($75,000) granted before the adjournment of that body. We were all doomed to disappointment, however, and feel that a grand opportunity has been lost, at least for a time.

The great necessity for some such scheme lies in the fact that so much time is lost to our citizens during the business hours of the day at the bridges.

The saddest phase of the hotel disaster at Buffalo, is of course, the loss of human life, and to us who have for years known one of the unfortunate victims, the blow comes home with especial force. Others who perished in that fiery furnace had friends equally near and dear to them; but few had so extended a range of acquaintance, as Robert S. Boyd, and fewer still, so large a proportion of warm friends. The great saving clause in the whole affair, the only redeeming feature, was the electrical alarm for waking the guests, and the promptness with which it was turned in by the night clerk, Mr. Wm. H. Alford, whose ready appreciation of the situation saved very many from cremation.

The Edison people here have for the past three or four years, endeavored to obtain a franchise from the city for the purpose of opening up a central plant incandescent system. The petition had grown sour and mouldy from age, as was generally thought, when suddenly, like a jack in the box, up it came, at the city council meeting of the 21st of March, and went through at lightning train speed. There was a remonstrance, but like all other ponderous bodies, once they get "set in their way," nothing stops a city council. The ordinance gives the right to open all streets, alleys, sidewalks, etc.; to go pretty much anywhere, out of sight. The company must extend its conductors and supply current for any district when ordered by the council, provided there is sufficient patronage in sight to pay six per cent. on the investment. The franchise is for 25 years. A bond of $50,000 is required to cover any damage to city property. The law was subsequently changed at the earnest request of its "off-sided" friends, so that only light and power should be furnished by the company, and the franchise should not be strained to allow the telephone and telegraph fellows to occupy the conduit, and the permission of property holders adjoining the sidewalks should be obtained before the conduits should be placed in the sidewalk area. As a whole, however, the act was accepted by the mayor, and has become a law.

For a long series of years, under Prof. Barrett, the stable doors of our fire department houses have been automatically opened by the release of an armature and the action of springs, at the first break in the circuit, when an alarm of fire is turned in. Like hundreds of such combinations a few years ago, this was a local application in a practical way, and no patent was applied for at the time. Since that time some one seems to have obtained a patent for this method of releasing the doors, and the Louisville *Commercial* of the 15th, contains an article which details the action of a syndicate claiming to own the patents aforesaid, and which swooped down upon Louisville with a claim of $24,000, as pay for its use past and future. Half a dozen towns have been assessed and paid the assessment, but Louisville don't seem to want to pay in that manner. The article says:

"It was a beautiful bluff, but the representatives of the syndicate will find themselves called and they'll lay down a bob-tail. Senator McDonald was brought along by the Indiana gougers for the purpose of strengthening the hand, and congressman Caruth was added on this side of the creek as additional strength to the layout. But the city is not to be bulldozed, and the representatives might as well pull up stakes and go to some smaller city and make their gigantic bluff. They tried it in Chicago, but it wouldn't work. Why don't they tackle New York, Philadelphia, Boston, and other large eastern cities."

All which goes to prove that the city don't purpose being bluffed into laying down quietly, and the local reporter needs a missionary to show him the wickedness of poker. Speaking of Louisville and its people, brings up the fact that Mr. Wm. H. Johnson, an old, old timer, electrical mechanician, something of an inventor, and always a genial, good fellow, has come to Chicago to remain, and taken charge of the construction work of the Electrical Supply Co. here.

We have had lots of speculation latterly, on the subject of consolidation of our central electric light plants. No less than four or five parties have been mentioned as anxious to merge the several interests, and run the whole as one organization. The parties named by rumor, are: the present Conduit company, which is successor to the former Sectional Electric Underground Co., the heads of the Chicago Telephone Co., the Western Electric Co., the Thomson-Houston Illuminating Co., the Southside Chicago Light Renting Co., and the Western Edison Co., under the new name.

A new Chicago firm is the Central Electric Co.; M. T. Greene, president, George A. McKinlock, treasurer, and Wm. H. McKinlock, secretary; the latter gentlemen from the Detroit Electrical Works. The firm is located at 38 and 40 LaSalle street. "All kinds of electrical appliances made and sold," covers the scope of the enterprise as concisely as possible.

CHICAGO, April 17th, 1887.

[FROM ANOTHER CORRESPONDENT.]

The New Building of the Chicago Telephone Company.—The Electrical Accumulator Company Open Business in Chicago.—Prof. Barrett's Investigation of the Dangers of Electric Lighting.—The American Electric Manufacturing Company to Open an Office in Chicago.—Fluctuations in the Price of Electric Light Carbons.—Electric Lights at Kankakee.—Reported Combination of Eastern Capital to Control Chicago Gas Interests and Introduce Electric Lighting.

THE Chicago Telephone Company have about completed their plans for the erection and furnishing of a seven-story office building, to be put up by them on their land at the northeast corner of Franklin and Washington streets, one of the most desirable locations in the city. It is expected to be finished and occupied early in the spring of 1888, and it is with pleasure that we give at this early date such details as may be had. The building will be fireproof throughout, the first story of stone and the remainder of pressed brick, and will cost in the neighborhood of $75,000 to $100,000. The fourth floor will be arranged for the general offices of the company; the superintendent, assistant superintendent, district construction foremen and repair departments, occupying the second floor, The basement and first story will be used for supplies and instruments, with the office of the storekeeper in the front part of the first floor. The operating room will be on the third floor. The Central Union Telephone Company will leave the Pullman building and occupy the sixth floor of the new building for their general offices. The building will be furnished with passenger and freight elevators. The company propose to put down a drawing-in system of 16 2½ inch iron pipes, from La Salle street, and will put in them Patterson cables of 200 conductors. There will be about 3,100 wires entering the building. The present offices on La Salle street, with 1,400 wires, and that at the corner of State and Randolph streets, with 800 wires, will be closed up and the wires brought into the new building. A new switch-board outfit will be purchased, but the style has not yet been determined upon. Besides the underground work contemplated, as above, a line of about 250 wires will be put down on West Madison street, from Halsted street to Ashland avenue, a distance of one mile. The Chicago Telephone company is now serving, in and around Chicago, about 6,000 subscribers, their subscription list in the city alone having about 4,300 names.

The Electrical Accumulator Company, of New York, have arranged for the development of their accumulator business in this section, and have opened an office at No. 227 La Salle street. Messrs. J. W. Johnson and A. C. Holland are associated with Mr. C. N. Fay in the management of this enterprise. Their first installation is now being placed in the factory of the Western Electric Company, and is intended to supply 50 incandescent lamps of 16 c. p. each.

Prof. J. P. Barrett, superintendent of the city fire department, has sent a circular letter to managers of telephone exchanges, and others, asking for information, with particulars as minute as possible, in relation to losses of life and property caused by electric light wires. He states in his letter that the question is an all important one, and that the dangers to life and property arising from improperly protected currents of electricity demand urgent attention; that in view of the facts he proposes to place before the national association of chief engineers, in September next, some suggestions tending to reduce these dangers to a minimum. The facts that Prof. Barrett will collect and summarize while he is studying this subject will be of wide interest. High tension currents are dangerous and ought to be kept within bounds, and most of the electric light systems now in vogue use high tension currents.

It is expected that the American Electric Manufacturing Company will soon have an office and salesroom in this city.

Digitized by Google

The president of the company said, last week, that they had decided to make Chicago their headquarters for western business.

Last week first-class electric light carbons were in the market at about $12 per 1,000. Now they are held at higher prices, and it is a matter of common report that purchasers will soon be at the mercy of Mr. E. C. Hawks, agent. If any one is doubtful as to the present strength of the combination, let him write to his favorite manufacturer for quotations. The manufacturers claim that while in competition they did not get a fair price for their product, and that the result has been a market full of inferior carbons, hurting their business. From a consumer's point of view, of course, good carbons are essential to good lighting, but there has been no difficulty in getting good carbons at low prices, and it comes hard now to accept the changed conditions. Carbon and the making of it into pencils do not appear to most people to be very easy matters to control, and consumers generally express the opinion that the manufacturers cannot long avoid competition.

Kankakee saw electric lights within its limits for the first time last Wednesday. This enterprising town wanted its streets well lighted, and a company was quickly formed, who selected a Western Electric outfit. All the lights have burned without a hitch since they were first started, and the people and their papers express themselves as delighted with the changed appearance of their streets these evenings.

Eastern capitalists seem to be fairly tumbling over each other in their haste to invest money in Chicago—so one of our daily papers tells its readers by way of comment upon its report of the attempt of a New York syndicate to purchase a controlling interest in the gas companies here. The plan is said to be to unite all of the gas companies into one combination, this combination to build electric light works in connection with each gas works, and thereby control and supply all the artificial lighting of the city. Gas companies can certainly do electric lighting in connection with their gas business at considerably less cost than independent companies. Such combinations are now working in many places, the number is constantly increasing, and the results are uniformly satisfactory. Has not the time come for the gas companies in large cities like this to furnish the right lights for the right places? Here our streets are without exception all lighted in the old-fashioned way, and our rivers, where light is needed so badly, are not lighted at all.

CHICAGO, April 19, 1887.

SAN FRANCISCO.

Flourishing Business on the Coast.—Electric Lighting and Electric Railways.—Opposition of the Gas Light Co. to Electric Lighting.—Franchises for Subways Still Sought.—Postal Telegraph Co.'s Affairs.—Dr. Cornelius Herz and his "Push Button" Telephone.

EVERYTHING in California is "booming" just now. Hamlets are becoming towns and cities, men who were content to be called farmers a few years ago, are now "landed proprietors," so on with fruit growers, wine growers and sheep herders. If the electric boom continues, not a town or village in the state will be without an electric light, and even farmers may attempt to generate electricity by the revolutions of their windmills. Electric railways are now engrossing public attention. The latest is an incorporated company to operate an electric railway between San Jose and Santa Clara, a distance of four miles, and if it proves satisfactory, another branch will be operated from San Jose to Congress Springs. It is thought the Daft system is the one determined upon, although the Short has many advocates and admirers. San Jose is justly called the "Garden City," and prettier drives than those to Santa Clara and Congress Springs are not to be found in California. As the climate is warm and free from fogs, it is an invalid's paradise; open electric cars would be liberally patronized at all seasons. The electric road in process of construction in this city, is no longer in doubt judging from the manner in which capitalists are looking for the stock; and instead of one we may look for many in San Francisco.

If the "sack" of the San Francisco Gas Light Co. does not allure honest supervisors from the path of virtue—which all politicians assure their constituents they intend to follow—the California Electric Light Co. will probably secure the contract for lighting this city for the next two years. Thieves, burglars, garroters, and some politicians, will unite with the "bosses" in opposing the electric light in favor of the gas, the "sack," and their own nefarious calling, but, as Cornwall is an old politician, and John Farren an ex-supervisor, and George Roe is familiar with Canadian "bull-dozing" the chances are that these wily veterans will be able to checkmate the opposition.

Mr. McGrew is again in the field for an underground conduit franchise; and Mr. Ladd, like the famous guard, never retreats, but hammers persistently on the supervisorial cranium.

The Postal Telegraph and Cable Co. are open to the East and to Europe, and are doing a very satisfactory eastern, with a first rate local business.

Mr. Samuel Rosener, who has been temporarily looking after Mr. Mackay's and his brother's interests on this coast—until a General Superintendent was appointed—has returned to his own field; carrying with him the esteem and respect of all who came in contact with him. It is to be regretted that there are few Roseners in the telegraph business. A man of wealth and commercial standing, he was as approachable and affable, as a gentleman usually is. Like his brother, Mr. Henry Rosener, he considered the laborer worthy of his hire, and no man worked overtime for them without extra compensation. Mr. D. S. Robeson is now General Superintendent of the Postal company on this coast. A very pleasant chat with him and a good look at his countenance, indicate a broad-gauge practical man—one well equipped to run a successful opposition. Although he would not outline the intentions of his company, Mr. Henry Rosener assured me it was their intention to build in all directions, and to secure other eastern outlets. With all this accomplished, the unbending Western Union Cederic may think it time to cut the collar of bondage from the necks of their operating Gurths.

I notice that "Doctor"—now Chevalier—Cornelius Herz, has astonished the king of the Belgians and the people of France, by his wonderful push-button telephone. The Doctor has been experimenting on this contrivance for years. Even while in San Francisco in '75 and '76, he was hard at work on it. His apparatus was of human shape, and the telephone was an ear just like the human ear, and when spoken to by the Doctor, a button dropped out of a pocket. It was so satisfactorily experimented with, that the late Milton S, Latham, Lyons the brewer, J. C. Flood, M. J. Keating, Geo. S. Ladd, Paul Seiler, and Stephen D. Field, took stock in the "push" of Doctor Herz, who was made general manager. So confident have they been of future success that they still hold the stock, except Mr. Field, who sold his out in Paris, years ago, even at a loss. Mr. J. Keating offered his shares on the Paris "Bourse" but could find no takers. Perhaps General Boulanger will endeavor to buy them, for fear Bismarck may thus secure a controlling interest in Herz's "push."

SAN FRANCISCO, April 15th, 1887.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, *115 Nassau Street, New York city.*

THE USE OF THE WORD "TELEPHONE."

[66].—In my historical paper on the word "Telephone," published in the ELECTRICIAN AND ELECTRICAL ENGINEER, for April, the concluding paragraph reads:

"I have thought it worth while, therefore, to make a compact record of the instances of its use otherwise which I have been able to find."

It occurs to me that I should explain that this paragraph refers only to its use in the English language. Sondre's system is also noticed in Brey's "Dizionario Enciclopedico," 1840, and Dingler, 1835, v. 58, p. 360; and as we find in "Der Praktische Machinen Constructeur," 1869, p. 281; "Deutsche Industrie Zeitung," 1869, p. 114, and Bryeriche's Industrie und Gewerbe-Blatt," 1871, p. 84, the ordinary speaking tube was known in Germany as "the Telephone."

These instances were referred to in the opinion of the Examiner who decided the telephone interferences.

BOSTON, Mass., April 6, 1887. T. D. LOCKWOOD.

A FURTHER WORD ON "UNDERWRITER" WIRE.

[67.]—I have read with much interest the report of the Electric Light Convention recently held in Philadelphia, and am glad to note the action taken in appointing a committee of competent gentlemen to investigate the question of insulating electric light wires. Now that the defective and dangerous condition of the present plants is admitted by the representatives of the electric light companies, there would seem to be no reasonable excuse for continuing the use of what is known as "underwriters wire."

Mr. Haskins recommends the employment of instruments for testing the insulation and conductivity of the circuits. In this he is evidently in advance of the times. The naked eye is the only instrument required at present. In my travels between the Rocky mountains and the Atlantic coast I have failed to discover a single case of what can be called first-class electric light construction. The wires employed being very heavy compared with telegraph and telephone wires, their supports should be of the

Digitized by Google

most substantial kind. The poles, on angles, are almost invariably insufficiently guyed, the poles not properly located, and in many instances, they will not remain in their proper position 24 hours. The wires soon become slack and come in contact with other wires and objects that destroy what little margin of insulation there may be. As originally strung, the wires are passed through tree tops and left in permanent connection with green limbs.

A short time since, I met a gentleman who has had as much experience in line construction probably as any one in this country, having visited every northern state and territory from ocean to ocean. He stated that he had found but one city where good electric light construction existed, and that, I believe, was Sandusky, Ohio. Even Broadway, New York city, with its iron poles will not pass inspection for first-class work. Electric light companies seem to be following in the footsteps of the early telephone companies. Almost every telephone system in the country required rebuilding within a period of six years. A well built city line will stand for at least 15 years.

I observe that at each convention some one who feels that electric light companies are much abused, will relieve himself by reading a paper upon "popular prejudice against electric light wires." While I am a stockholder in an electric light company which uses the "underwriters wire," I hope this "popular prejudice," as it is termed, will continue until there is not an inch of uninsulated electric light wire in existence. It is, or should be, the practice to adopt all reasonable means for the protection of life and property when employing an element of danger in every day business affairs. You might as well use pot metal boilers for steam engines and say it is unjust popular prejudice that condemns it.

To string an uninsulated wire for arc lighting along our streets, which are thronged with people, when it is positively known that the currents they convey will destroy the life of any person coming in contact with them, is an outrage that should not be permitted. These dangerous wires can be easily insulated, and there is no good excuse or reason for their present dangerous condition. There is not a lineman in the employ of any telegraph or telephone company in our principal cities whose life is safe for a day, and we have reached a period when it is almost impossible to get a man to make repairs to broken wires after dark if there are any electric light wires in the immediate neighborhood. An instance recently occurred in this city where the fire department cut 20 telegraph wires on a trunk route at 6 o'clock in the evening. The fire was extinguished before it did much damage, but the wires remained on the ground all night because there were electric light wires in close proximity, and the linemen would not work fearing the wires they were expected to handle would accidentally come in contact with the electric light wires. A few weeks ago a Western Union lineman was instantly killed at Detroit, Mich., while standing upon the ground reeling up a wire that was being taken down. By accident it came in contact with an electric light wire. A similar fatal accident happened to a telephone lineman in this city.

It is no wonder the insurance companies are groping around in the dark in regard to the dangers of electric lighting. It is not so much a question of how properly to wire a building to make it safe, but how to keep the electric light currents from entering the building over other wires through crosses that may occur between the electric light wires and other systems of wires that are present in every city. Buildings will never be safe from these dangerous currents until properly insulated wires are used for every part of the circuit, both out and in doors. If insurance companies will take up the subject from this point of view, they will get at the root of the danger.

I am glad Mr. Haskins was so open and frank in his condemnation of the insulation that is almost invariably used. His statements contrast nicely with those of some other Chicago gentlemen who recently testified as electric light experts. The following is a sample: "I cannot conceive of a condition where there would be any danger resulting to persons or property from contact with, or the derangement of an electric light wire, such as the 'underwriters wire.' It would not be dangerous for a person to hold in his hands an uninsulated wire conveying a current sufficient to operate 50 arc lights and have the wire cut between his hands," etc., etc. Gentlemen, don't swear too strongly in this direction. If the orthodox doctrine of a future life be the correct one, some of you will have a fearful time making crooked things straight before you pass through the gates.

Electric lighting should not be dangerous. It can be made one of the safest modes of illumination. The reason it is unsafe at present is because the plants have been so constructed as to give a maximum degree of danger and interruption. The scientific laws which should govern such construction have been largely disregarded. It would seem that the plants were constructed to sell, and if they worked a week or a month, the object of the projectors was accomplished.

The incandescent systems are also defective as a rule. The "underwriters wire" finds favor here also, and a pint of water judiciously spilled will extinguish the lights and start a conflagration. During a rain on February 1st last, at Louisville, Ky., the electric light wires came in contact with a fire alarm wire, and the result was a damage of $7,000 to the fire alarm system, and the business portion of the city left without any protection.

Since my last communication upon this subject, Mr. W. H. Brockway, superintendent of the Minneapolis company, lost his life from a shock received from an electric light wire. Notwithstanding the long list of fatal cases reported, and the losses from fires, the electric light companies still persist in stringing their uninsulated wires above, below, between, and around, every other class of wires found in cities. The situation is becoming critical in the extreme, and it behooves the committee appointed by the Philadelphia convention to act promptly.

In states where the legislatures have prohibited the use of uninsulated wire, any aggrieved corporation or individual can enjoin electric light companies from using the "underwriters" or any other imperfectly insulated wire, and this action will certainly be taken by telegraph and telephone companies if the present state of affairs continues to exist.

Very respectfully, I. N. MILLER.

CINCINNATI, Ohio, April 15, 1887.

A CORRECTION.

[68.]—An injustice was done the Mather dynamo in the "Note on the Performance of Some Dynamos" published in the ELECTRICIAN AND ELECTRICAL ENGINEER of April. The figures for volts per foot of wire on armature, volts per foot of wire and per unit periphery velocity, and volts per foot and per revolution were calculated on a basis of double the length of wire actually on the armature. Thus the results are but half their true value in this case, and the data for the Mather machine in the table should read:

Machine.	Rev. per Minute.	Velocities.	I.	II.	III.	E.M.F.	Current.
Mather	2750	3200	.520	.0098	.00020	125	40

It is but due the machine, that correction should be made.

Respectfully yours, D. C. JACKSON.

PHYSICAL LABORATORY, CORNELL UNIVERSITY, April 18th, 1887.

LITERATURE.

REVIEWS.

L'Annee Électrique, ou exposé annuel des travaux scientifiques des inventions et des principales applications de l'électricité a l'industrie et aux arts. Par Ph. Delahaye. Troisieme Année. Paris: Baudry et Cie. Janvier, 1887.

A WELL classified account of salient features in electrical progress during the year 1886 is presented in M. Delahaye's annual. It is very convenient to have thus brought together in a compact volume, notices of investigations and inventions of which the original accounts are scattered through a large number of publications in several languages. Nearly one-half the volume is devoted to electric lighting, storage batteries and electric motors; a space not too great for the rapid and striking development recently accomplished in those fields. American research and investigation is but scantily reported. This is doubtless due, in large measure, to the fact that American electricians and inventors are for the most part too busily engaged in practical work to find leisure for writing out and publishing the results of their work.

The usefulness of M. Delahaye's yearly volume would be much increased by supplying simple illustrations and diagrams in many cases.

SOME RECENT INSTRUCTION BOOKS.

Elements of Static Electricity, with a Full Description of the Holtz and Töpler Machines and their Mode of Operating. By Philip Atkinson, A. M., Ph. D. New York: W. J. Johnston. 228 pp., 12mo., illustrated.

Modern Electricity and Magnetism, Theoretically and Practically Considered. Being the Chapter on Electricity from the Elements of Natural Philosophy. By Elroy M. Avery, Ph. D. New York and Chicago: Sheldon & Company. 366 pp., 12mo., illustrated.

Short Lectures to Electrical Artizans. Being a Course of Experimental Lectures to a Practical Audience. By J. A. Fleming, M. A., D. Sc. (Lond.). London and New York: E. & F. N. Spon. 206 pp. 12mo., illustrated.

THE phenomena of static electricity occupy but little of the attention of electricians of the present day, owing to the rapid development of commercial uses for voltaic and dynamic electricity. But to scientific investigators and students of electricity

Digitized by Google

there is interest in every branch of it. Mr. Atkinson has obviously devoted much study and experiment to static electricity and has produced in small compass a volume setting forth its principal properties clearly, illustrating them by descriptions of experiments, and making many suggestive comments. As stated in the introduction "the principles of electricity are presented untrammeled, as far as possible, by mathematical formulæ, so as to meet the requirements of a large class who have not the time or opportunity to master the intricacies of formulæ." Illustrated descriptions are given of the Holtz and Töpler machines, and of Sir Wm. Thomson's electrometers. To the student and the general reader interested in scientific topics Mr. Atkinson's volume will be both profitable and pleasant reading.

Dr. Avery's excerpt from his *Elements of Natural Philosophy* is a well arranged class book for use in schools. A competent instructor with a reasonable outfit of apparatus at hand, using this manual as a text book, and following its orderly presentation of theory and illustration could easily impart to his pupils a sufficiently comprehensive knowledge of electricity for all but professional students. Perhaps the large space assigned to frictional electricity is rather disproportionate in view of the much greater practical importance of galvanic and magneto electricity in the arts of life. The modern dynamo-electric machine receives but scant treatment in the section on induced electricity, and the telephone still less; the microphone is not mentioned at all. Duplex, quadruplex and multiplex telegraphy are dismissed in a paragraph (446) of fifteen lines referring the student to technical works on telegraphy for explanations of those systems. While details of practical applications of electricity may not be strictly required in a school text book, a moderate space devoted to illustrations and explanations of methods so important as those above named would greatly enhance the usefulness and interest of the volume. The introductory chapter, giving concisely many useful definitions of terms used in general physics and of the units of the metric system, furnishes a good preparation for the student. Resort to measurement and calculation by the student is inculcated throughout the volume; each section being followed by a series of exercises or problems involving the principles set forth in the text. While Dr. Avery's book might with advantage be more inclusive, as we have suggested, it is admirable in its methods of presenting and illustrating the phenomena and principles included in its scheme.

As indicated in its title, Dr. Fleming's book is addressed to a class who already know something of electricity and magnetism. The origin of the volume is set forth by the author in the preface as follows:—"Being desirous that practical training should be supplemented by some attention to theory, Mr. R. E. B. Crompton requested me to give during the past winter some lectures on subjects connected with the principles underlying modern electrical engineering to the pupils and workmen associated with his firm, and the following pages contain the transcript of these lectures delivered at Chelmsford. Confident that the right direction for technical training is to bring home to the craftsman the scientific principles involved in daily work which passes under his hands, the subjects which most naturally claimed attention were those involved in every day experience of the audience addressed."

Following the line thus indicated the topics of the lectures are confined, for the most part, to the principles of electromagnetism and magneto or dynamic electricity. We can perhaps best give an idea of the scope of the book by quoting the headings of the first and the last of the nine lectures. Lecture I. Magnetization—Magnetic Polarity—Lines of Magnetic Force—Measurement of Magnetic fields—Magnetic Resistance—Permeability and Susceptibility—Saturation—Magnetic Theories. Lecture IX. Electro-Motors—Measurement of Work—Efficiency of Motors—Re-action Between Armature and Field Magnets—Counter-Electromotive Force—Measurement of Efficiency of Motors. The series of lectures constitute an extremely lucid exposition of the principles employed in the construction of dynamos and electric motors, together with adequate notice of secondary generators and storage batteries. Typical forms of measuring apparatus are described and explained, and one entire lecture is devoted to the C. G. S. system of units and measurement. In plan and style Dr. Fleming has happily avoided the too common error, in books addressed to classes less instructed than the authors, of consciously writing down to an assumed lower level of comprehension. He rightly addresses electrical artizans as already possessed of more than the average current knowledge of electrical phenomena, and refrains from invoking afresh the shade of Thales with his *elektron*, and from repeating the time honored elementary descriptions and experiments accessible in school books. Without resorting to mathematics beyond simple arithmetic and the most elementary algebra, the lectures convey clear, accurate and precise information upon the general theories and principles involved in the electrical engineering of the day. The volume can be commended to electrical artizans in America, and to such general readers as desire to keep informed in technical progress.

PERIODICALS.

We have received No. 2. vol. i. of the new monthly journal published by the students of Sibley College of Cornell University, under the fanciful title *The Crank*. The number in hand is chiefly devoted to a pleasant account of the recent inspection tours of the engineering classes, including that of the class in electrical engineering, of which we published the programme in our April number. The Cornell students are welcome in the field of journalism, but they must not use the phrase "in our very midst" and expect to escape the vigilant eye of that stern critic of English grammar, the New York *Sun*.

CATALOGUES AND PAMPHLETS RECEIVED.

The Standard Underground Cable Company issue a new circular for 1887, describing and illustrating a large variety of electric cables, covering about all uses for which insulated and protected conductors are required. The Waring Cables, made by this company, have come into extensive use during the past few years, and the circular contains many notices, commendatory of their qualities, from electricians and others who have had experience with them.

The Safety Electric Railway and Power Co. (Daft System) issue a handsome new circular which has reached our hands. In addition to illustrated description of Electric Dynamos and Motors for a variety of uses, the pamphlet contains much matter of interest on Electric Railway, including a very full description of the Baltimore and Hampden Electric Railways, which was put in operation September 1st, 1885. A map of the route of this road is given.

We have received the illustrated catalogue and price list of Messrs. E. E. Garvin & Co., manufacturers of machinery and machinists tools. The descriptions and illustrations exhibit a wide variety of machines and appliances adapted to many branches of manufacture. The Messrs. Garvin are well known to purchasers of machinery and tools.

We have received from Messrs. W. R. Ostrander & Co., a copy of the fifth edition of their catalogue of Speaking Tube Apparatus, Electric Bells and Annunciators, comprising a large and very complete list of pneumatic and electric household appliances. Electric Gas Lighting devices are included in their lists. The Catalogue is well and profusely illustrated.

ELECTRICAL NEWS AND NOTES.

OBITUARY.

George H. Grace.

MR. GEORGE H. GRACE died at his home, Easton, Pa., April 13th, after a long and courageous struggle against disease involving great suffering. He never lost heart. No one who was privileged to see him in his sick chamber during the past year will be likely to forget his serenity and courage. Though prostrate and in bed, he continued to look after his business—the charge of the telegraph lines of the New Jersey Central Railroad system—receiving visits at the bedside from his clerks, hearing their reports, and giving them instructions.

Mr. Grace had been a telegrapher from boyhood, having commenced his service as a messenger in the New York office of the House Telegraph Co. in 1851. He advanced rapidly, and in 1857 became manager of the Petersburg, Va., office of the Morris Southern lines. After service with the American Telegraph Company, beginning in 1860, he became in 1866 superintendent of the Insulated Lines Telegraph Company, afterwards called the Franklin, working a number of wires from Boston to Washington. Subsequently he was made superintendent, successively, of the Bankers and Brokers, the National and the Automatic Telegraph Companies. In July, 1874, Mr. Grace accepted the position of General Superintendent of the Southern & Atlantic Telegraph Company. He found a congenial task in pushing forward the work of this company which, with connections north and east of Washington over the lines of the Franklin and Atlantic and Pacific companies, was developing a vigorous opposition to the Western Union company. Mr. Grace was instrumental in a successful negotiation for his company of a connection with the Western Union for business north of Washington in April 1874; an arrangement which culminated in the leasing of the Southern and Atlantic lines to the Western Union company in 1876.

It will be noted that during a considerable period Mr. Grace was engaged in enterprises competing with the Western Union Telegraph Company. His energetic character well fitted him for such work. After the virtual absorption of the Southern and Atlantic in the Western Union company Mr. Grace entered the service of the latter, in which he continued till his death.

Mr. Grace's personality made a strong impression upon all who came in contact with him. He combined much force with great activity, was positive in his views and vigorous in whatever he undertook. By his warm heart and genial companionableness he made a host of friends who will be saddened by his death, and keep his memory green in pleasant reminiscence.

ANNUAL REPORT OF THE AMERICAN BELL TELEPHONE CO.

OFFICE OF THE AMERICAN BELL TELEPHONE CO.,
BOSTON, March 29, 1887.

To the Stockholders:

Our business for the year ending December 31, 1886, was marked by an improvement over the previous year, especially in

In the hands of licensees under rental	237,728	298,580	325,574	330,040	358,518	23,478

EXCHANGE CONNECTIONS.

The estimated average number of exchange connections daily in the United States is	856,454
Or a total per year of	312,605,710
The number of daily calls per subscriber varies in different exchanges from 2 to 15, the average throughout the United States being	5 82-100
As compared with	5 43-100

the number reported last year, an increase of 7 per cent.

The average cost to the subscriber varies, according to the size of the exchange, and character of the service, from 2 to 7 cents per connection.

EXTRA-TERRITORIAL BUSINESS.

The average daily number of extra-territorial connections is	7,402
Or a total per year of	2,701,730
The extra-territorial earnings for the year amounted to	$565,514 85
Of which this company's share is	$75,617 30
An increase over 1885 of	$2,208 02

In the case of six companies which have not reported for the entire twelve months, the statement has been completed from the average for the months reported.

It will be noted that the number of miles of wire underground has materially increased, and we expect further large additions to the underground mileage in the current year, especially in New York, where the subway commission has made arrangements for the working of an underground system, which will meet the requirements of the wire companies.

The legality of the plan adopted by them has been questioned in the courts, and further legislation may be needed before the work can be completed; but as there is a strong public desire for the burying of wires to the greatest practicable extent, the necessary legislation will probably be obtained and the work go forward. This will involve a heavy outlay by the Metropolitan Telephone and Telegraph Co., and the subject has been under careful consideration by the directors of that company and by our Mr. Davis; and they are prepared to put a large part of their wires into subway conduits as soon as the obstacles referred to are removed.

Following the policy outlined in the last report in respect to licensed companies operating in territory of little value where it was found difficult to build up a profitable business, we have modified our contract relations with several of such companies, and have negotiations in progress with several more, which will, in our judgment, place these companies upon a sound footing, will promote friendly relations, and will serve to encourage the proper development of the business.

The concessions made involve yielding a certain share of the profits immediately accruing to these companies, but will, we believe, in the long run prove of mutual advantage to ourselves and the companies interested.

Terminal facilities have finally been secured, within a few months, in Philadelphia, for the long line service, and arrangements completed for giving facilities for conversation to New York and other important points. Several private lines are already under contract between Philadelphia and New York, and we shall this year be able to go far in ascertaining the value of this class of business.

The delay in getting facilities granted in Philadelphia has prevented us from determining this question in a practical manner; but we consider it of sufficient importance to connect Boston with New York to warrant building that line without waiting for the commercial result in the Philadelphia and New York line, and are taking steps to complete it during the present year.

The treasurer's statement shows—

Gross earnings for the year from all sources		$3,097,000 91
Expenses		1,149,717 79
Net earnings		$1,947,283 12
Miscellaneous credits		26,067 64
Total		$1,973,350 76
Regular dividends paid	$1,176,252 00	
Extra dividends paid	392,084 00	
Total	$1,568,336 00	
Reserve for depreciation of instruments	117,754 59	
		1,686,090 59
Balance to surplus account		$287,260 17
Total surplus		$1,491,380 18

The Canadian company continues to do extremely well; it has increased its subscribers during the year from 9,614 to 11,600, and its net earnings from $158,000 to $190,565.83, and although the Blake transmitter patent, as well as the Bell patents, has been declared void, the business of the company seems to be on a most healthy and prosperous footing.

* * * * *

The operation of the Indiana law regulating rates has proved to be as mischievous to the public as was predicted. It, of course, at once stopped absolutely any extension of business, and checked that steady improvement which is constantly going on towards greater efficiency and convenience to the public in the conduct of the business. The service was so crippled that strong popular feeling showed itself, urging the repeal of the law. The bill for its repeal passed the house by a very large majority, and went to its third reading in the senate, when the political complications arising out of the questions relating to the lieutenant-governorship arrested all business during the remainder of the term of the session.

Bills for the regulation of telephone rates have during the past winter been introduced into a number of the state legislatures. In these cases where final action has been had, the measures have been rejected, and a disposition seems to be generally felt against imposing restrictions which it is not customary to place upon other branches of business.

At the present time, when it is becoming necessary for all the large telephone companies to incur heavy outlays for underground wire work, it certainly seems that they should be relieved from the danger of having measures adopted which would prevent all profitable development of the business.

Our company and our licensees are proposing to make large outlays to give increased facilities for telephone connection, which there would be no temptation to provide if there were much probability that the states could and would place restrictions upon prices for that which we shall have to sell.

By act of 1886, chapter 270, a modification was made in the law under which this company is taxed in Massachusetts, the result of which has been to increase our tax very considerably; that laid on the 1st of May, 1886, amounts to $74,846.98.

The patent division continues its work of digesting American and British patents relating to electrical subjects, including not only inventions claimed, but inventions described in specifications unclaimed.

It has also prepared during the year and reported on a large number of subjects submitted by the officers of the company.

Digitized by Google

The electrical division has been much occupied in experimental work, at the instance of counsel engaged in our various litigations.

It has also begun and made considerable progress in an extended series of experiments on pole lines and on mixed cables and pole lines for calculating the dimensions of pole wires and cables forming the alternate links in any chain of telephonic communication.

The mechanical department has given much time to studying long-distance transmitters, and to the general question of transmitters of the granular carbon type.

It has also devised a suitable form of instrument for use in mines, and a form for the use of divers.

* * * * *

The business of 1887 has opened well, and the directors look with confidence for a prosperous year.

For the directors,

W. H. FORBES, *President.*

A RED-HOT TELEPHONE TRANSMITTER.

Professor G. Forbes and Mr. John Munro, have recently made some experiments with a red-hot wire as a telephone transmitter, an account of which has been communicated to the Royal Society. A fine platinum wire, from .001 to .005 inch in diameter, and several inches long, was included in the circuit of a charged accumulator, and the primary wire of an induction coil. A receiving telephone was connected in circuit with the secondary wire of the induction coil. The battery power was such that the fine wire in the primary circuit was heated to a high temperature and rendered incandescent. When in this condition, on speaking to it the words could be heard in the receiving telephone. The explanation of the phenomenon is, that the sound waves passing the incandescent wire in quick succession altered its resistance by cooling, and thus varied the strength of current in the primary circuit. The fluctuations of current thus caused excited corresponding fluctuations in the secondary circuit, and these reproduced the voice in the receiver. Spiral wires in the form of watch springs, of steel and platinum iridium, were tried in place of the straight wire with some success. An india-rubber diaphragm was also interposed between the voice and the heated wire, and found to influence the wire like the direct voice. Mechanical vibration did not affect the apparatus.

ELECTRICAL FESTIVITIES.

DINNER OF THE ELECTRIC CLUB.

THE anniversary dinner of the Electric Club was held at the Hotel Dam (Union Square) Thursday evening, April 21st. About 100 members and friends sat down to meat at half-past seven o'clock and did not rise till midnight. The dinner was of the best, and fully deserved the two hours and a half occupied in its enjoyment. General sociability promoted the leisurely disposition of choice viands and cheering cups till ten o'clock, when Mr. C. E. Dutton, toast master, rapped the table, and with much humor and felicity announced "Our Club." The toast was responded to by Mr. C. L. Buckingham, in a vein of quiet and veiled humor greatly enjoyed by the attentive listeners. Having been warned to confine himself to the past, or at least, not to trench upon the future, he drew from the adventures of Gulliver many significant allusions to the affairs of the club and its members. Dr. Otto A. Moses, replied to the next toast "Our Future." His remarks were happily in keeping with the spirit of the occasion; he predicted a bright future for the club—but not too bright in view of the growth of its membership from 13 to 220 during its first year. "Electrical Nomenclature" brought to his feet Mr. W. S. Hine, who responded in verse. His chaotic humor and felicitous rhyming kept the room in a roar of laughter during the entire reading—Our "good gray poet" will have to look to his laurels as the champion in catalogues in verse. Mr. C. J. H. Woodbury, of Boston, was called for "The Barbarians of the Outside World." From the point of view of one inside the world of electricity, Mr. Woodbury recited a number of unfortunate experiences met with by outsiders in meddling with electric and other matters which they did not understand. Along with his jokes and anecdotes Mr. Woodbury presented much solid and valuable suggestion in his references to the growth of electrical arts, particularly to the results accomplished in this country by the joint efforts of scientific men and artizans of skill and common sense. Mr. H. J. W. Dam was permitted to make a "Gentle Protest from the Barbarians," which he did effectively. After a shower of witticisms he proffered a pathetic appeal to electricians to wipe out their jargon, and to use terms current in common English.

Among the guests of the club were Mr. Marshall P. Wilder and Mr. Edward Fabian. At various stages of the evening Mr. Wilder convulsed the company with anecdotes recited as only he can do it. Mr. Fabian contributed a number of remarkably effective recitations. Lieut. F. W. Toppan and Mr. G. M. Phelps, Jr., of the club, furnished one a song and the other a pianoforte piece

The evening will be pleasantly remembered by all who were fortunate enough to be present. Many old friends met, and many new and pleasant acquaintanceships were acquired.

Preceding the dinner the annual election of the club was held, resulting as below:—

President—H. C. Davis; Vice-Presidents—Geo. W. Hebard, John B. Powell, Thomas A. Edison, Geo. L. Beetle; Secretary—Charles W. Price; Treasurer, Andrew J. Dam; Board of Managers—Henry D. Stanley, M. W. Goodyear, E. T. Gilliland, Willard L. Candee, Chas. Dutton, Cyrus O. Baker, Jr., H. B. Thayer, E. T. Lynch, Jr., Thomas L. Fowler, Stephen D. Field, Henry A. Reed, Fred. A. Gilbert, Geo. B. Coggeshall. Committee on Membership—Henry Hine, Geo. Worthington, Geo. T. Manson, Henry D. Lyman, Jackson Bailey.

ENGLISH ELECTRICIANS ENJOY THEMSELVES.

The following notice is from the *Electrical Review* (London):

"*The Electro-Harmonic Society.*—The first smoking concert of this newly formed society took place on the evening of Friday last in the banquet room of St. James's hall restaurant, Mr. C. E. Spagnoletti, presiding. As many of our readers are aware, the society has been promoted with the object of occasionally bringing together the electrical fraternity and their friends for the purpose of enjoying social intercourse, unencumbered by the trammels of business, and to listen to good music, which hath charms to soothe the savage breast (not an unusual possession in these days of keen competition), discoursed by exponents of proved ability; and, if a correct judgment can be pronounced from the impressions gathered on the opening night, we think that a long-felt want has been supplied. A capital programme had been provided by the musical directors, and the Electro-Harmonic Society listened with evident pleasure to several songs and glees, performed in an admirable manner by Messrs. Dalzell, Kift, Bevan and Brown. Mr. Wilhelm Ganz, whose name alone went far towards ensuring success, most kindly placed his valuable services at the disposal of the society, and played the "Sonata Pathétique" of Beethoven, in addition to some lighter selections. During the interval, Mr. Spagnoletti, who has been untiring in his efforts in support of the society, explained briefly the objects which had brought the members together, and shortly before 10.30 the concert came to a close, amidst general expressions of satisfaction from the assembly."

Total for Australia			36,098

THE GOVERNMENT TELEPHONE SUIT.

The filing of the American Bell Telephone Co.'s demurrer is reported in a despatch to the *N. Y. Evening Post*, of April 25th, as follows:

The demurrer of the defendant in the great suit of the United States against the American Bell Telephone Co. was filed in the United States Circuit Court this forenoon. It assigns as the grounds of the demurrer in substance the following: 1. The bill is multifarious, in that it conjoins allegations and prayers for relief in respect to patent No. 174,465, dated March 7, 1876, and allegations and prayers for relief in respect of patent No. 186,787, dated January 30, 1877. 2. The bill does not point out and specify which of the persons patents and publications referred to in its schedules anticipate each of the inventions claimed in the said two patents respectively nor in the several claims of each, it appearing by said schedule that some of the patents and publications therein referred to are subsequent in date to both the said patents to Bell.

To so much of the bills as refers to patent No. 174,465, dated March 7, 1876, the defendant demurs for the following cause: 1. The plaintiff does not show any power or authority, and no power or authority in law exists in any person or party, or any court, to bring said suit, nor to entertain the same, nor to give the relief therein prayed, nor any relief thereunder, or touching the subject-matter thereof. 2. The plaintiff has not made or stated a case which calls upon or justifies this court in the exercise of this discretion to permit this bill to be entertained. 3. Nor a case which entitles it in a court of equity to the relief prayed for. 4. Nor, as against this defendant the American Bell Telephone Co., to the relief prayed for or any relief whatever. 5. The case stated in and by the bill is one which, as against this defendant, the assignee of said Bell patents, should have been prosecuted (if at all) with the utmost diligence; whereas, as against this defendant, it is a stale claim, contrary to equity and good conscience, and one which, by reason of the gross laches, and delay in presenting it, a court of equity ought not to entertain.

The demurrer to the part of the bill which refers to patent No. 186,787, dated January 30, 1887, assigned the same causes for demurrer as are assigned in the demurrer to the patent numbered 174,465. The defendant then demurs to each and every charge in the bill on the ground that it does not show the patent to be void, and because the allegations therein contained, if true, would not entitle the plaintiff to the relief prayed for, nor to any relief in a court of equity, because the bill does not set forth any fraud in procuring said patent, nor specifically set forth what acts, if any, the complainant relies on as constituting fraud in procuring said patents, or when, how, from whom, or by what means the complainant first had knowledge or notice of each alleged fact; nor why, with due diligence, it would not have learned them earlier. There is also a prayer that the demurrer may be taken as a separate demurrer on each of said grounds to each allegation as if repeated in a separate form to each.

The argument on this demurrer will be set down for the first Monday in May, but at that time there will be no hearing, but probably a date for argument will be then fixed upon unless an agreement as to the time is made otherwise between counsel.

THE BALTIMORE AND OHIO TELEGRAPH CO. IN ITS NEW QUARTERS.

The main office and operating room of the Baltimore and Ohio Telegraph Co. are now removed from No. 63 Broadway to the building at Broadway and Canal street, formerly known as the Brandreth House. The operating room occupies the entire top floor, and the floor immediately below it is mostly taken up by the battery rooms. In the operating room are 310 desks, with single, duplex and quadruplex instruments.

The main switch-board is composed of five sections, into each of which enter 50 wires, connecting with various parts of the country. Besides this, there is another switch-board for connecting wires with important receiving and distributing points like the Produce and Stock exchanges. A novel feature of the room is a distributing railway system by means of which messages are sent to and fro between the clerical department and all parts of the room in a few seconds. It consists of little carrier-clips traveling over wires suspended overhead. It is constructed on the same principle as the cash railways in the large dry goods stores, except that the wires are strung on the level instead of an incline, and the carriers are shot to and fro by an ingenious combination of steel and rubber springs.

GERMAN PROGRESS IN ELECTRIC LIGHTING.

Kuhlow's German Trade Review enters a strong plea for German progress in electric lighting. A few years ago, England and France, after the United States, says our contemporary, excelled all other countries as far as the application of the electric light was concerned. What a change the last few years has brought is evident from the fact that Germany with 250,000 incandescent lamps is now in front of both these countries, and running a close race with even the United States. The progress we are making is decidedly rapid. Town after town is being equipped with central stations, while numbers of others are proposing to introduce the light on more or less extensive scales. Such towns as Hanover, Lübeck, Hamburg, and Breslau have arranged for extensive installations, while Dresden is only awaiting the result of the application of the Zipernowsky transformer system in Hanover before embarking on a similar enterprise. In Berlin the Stadtische Co. will shortly erect two new stations calculated to supply 15,000 lamps, besides further extending the existing ones. Hitherto the Edison lamp has always been in use, but in the new installations the Khotinsky lamp will be given a trial. It is said to be more durable and require less current than those of other systems, and on that account has found great acceptance on board our war vessels for both lighting and signaling purposes.—*The Engineer* (Glasgow).

PERSONAL MENTION.

We are gratified to receive with our copy of the *Electrician* (London) of April 8th, an excellent engraved portrait of Mr. William H. Preece, Electrician of the British Postal Telegraphs. Mr. Preece is well known to American electricians, through his distinguished services in improving telegraphic methods in Great Britain, as well as through his numerous contributions to the literature of electrical investigation and practice. Many of our readers will recall his genial presence on his visits to America some years ago. He left here many friends who would be glad to welcome him again.

Another instance of the not infrequent withdrawals from the service of the patent office of able and experienced men to engage in more remunerative pursuits, is to be noted in the resignation of Mr. C. J. Kintner, sometime principal examiner in electricity. Mr. Kintner has become associated in partnership with Mr. J. A. Wiedersheim, of Philadelphia, under the firm name of Wiedersheim & Kintner, solicitors of patents. Mr. Wiedersheim opened his office in Philadelphia 20 years ago. His increasing business requires further expert service, and to that end, he has secured the co-operation of Mr. Kintner, whose admirable qualifications are widely known; particularly in respect to electrical inventions. Mr. Kintner may justly value highly the commendation of his "learning, intelligence and skill," expressed by the Commissioner of Patents and the Secretary of the Interior in accepting his resignation.

RAILLERY.

Railroad president to the general attorney for the road—"Mr Blackstone, please tell us in your honest opinion of the interstate commerce bill—does the law prohibit our giving any passes to newspaper men?"

General counsel—"Do you want to continue the passes?"

President—"No, I don't."

Counsel—"Well, then, the law plainly enough prohibits issuing such passes."—[*Exchange.*]

ELECTRIC LIGHT AND POWER.

The Girard Trust, of Philadelphia, has determined to light the Girard College grounds and vicinity by means of seven electric light towers, each to be 125 ft. high and to be supplied with five or six lamps. Bids for the erection of the towers were opened, and the contract awarded to the Fort Wayne Jenny Electric Co., at $10,750. The other bidders were: Brush Electric Co., $10,936.55. U. S. Electric Light Co., $14,440, and the Thomson-Houston Electric Light Co., $13,291.50.

The Pawtucket Gas Light Co., Pawtucket, R. I., has decided upon the introduction of the electric light, and will put in a plant at once.

The American Electrical Manufacturing Co., New York city, will remove its offices, about May 1st, to the new building of the Metropolitan Telephone and Telegraph Co., on Cortlandt street. The American company has secured the entire second floor of this building, which will afford it abundant facilities for proper display of its specialties, and also allow sufficient room for its executive offices.

The introduction of the electric light is not always, apparently, an unmixed benefit. Some time ago electric lights were placed in front of the treasury and other public buildings in Washington, and a fine and striking effect is said to have been produced. Unfortunately, however, spiders discovered that game is plentiful in the vicinity of the new lights, and that they may there ply their craft successfully both day and night. In consequence, as Mr. G. Thompson writes to *Science*, their webs are so thick and numerous that portions of the architectural ornamentation are no longer visible, and when the webs are torn down by the wind, or fall from decay, the refuse gives a dingy and dirty appearance to everything it comes in contact with.

The St. Paul Gas Light Co., St. Paul, Minn., reports its electric lighting business as flourishing.

The Empire Electric Light Co., of Atlanta, Ga., will put in a plant.

The ownership of the Fuller-Wood electrical patents has passed entirely into the hands of the American Electric Manufacturing Co.

The Schuyler Electric Light Co., of Hartford, Conn., has reorganized and has a new charter. Charles E. Dustin is president, and C. H. Sewall, secretary.

The Heisler Electric Light Works, St. Louis, have erected a new two-story brick building immediately in front of their present offices, on South 7th street, and will use it for office and shop purposes. The company are quite busy throughout their extensive establishment.

The Wellsboro Heat and Power Company will establish an electric plant at Wellsboro, Pa., the coming summer. Anton Hardt and S. Harrison, are interested.

The United States Electric Lighting Company, Washington, D. C., is erecting an electric plant.

William Carroll, Matteawan, N. Y., contemplates establishing an electric light plant in Fishkill Landing, N. Y.

The Parkersburg Electric Light and Power Co., Parkersburg, W. Va., has contracted for the Westinghouse system, and will be in operation shortly.

The Hempstead Gas Light Co., Hempstead, L. I., will adopt an electric lighting system.

There are estimated to be 4,000 arc and 20,000 incandescent electric lamps in service in the city of Philadelphia.

The Electric Improvement Co., of California, has been incorporated in San Francisco, for the purpose of buying and selling inventions for electric motors and illuminants, and the manufacture of apparatus. Capital stock, $5,000,000 in $10 shares. Directors; F. W. Sharon, J. B. Randol, L. T. Haggin, A. J. Bowie, Jr., H. C. Dwyer, W. H. Howard, and Frank Butterworth.

The Edison plant at Brockton, Mass., is to be enlarged to nearly double its present capacity.

Port Jervis, N. Y., will be lighted by electricity. J. H. Dimmich is interested.

Carter, Shepherd & Co., Hannibal, Mo., contemplate establishing an electric plant for their mill.

The U. S. Electric Lighting Co., of Washington, D. C., is erecting its plant.

The Birmingham (Conn.), Electric Light Works were overrun with rats until the superintendent had a happy thought. To wires attached to dynamos he fastened bits of meat and scattered them about. The rats smelled the meat, nibbled, and—good by rats.

Foreign.

Austria.—Statistics recently published on the telegraphic communication throughout the empire, show that during the past year a total of 6,351,363 telegrams were transmitted, of which number 1,920,000 were local messages in the Vienna district. The total receipts amounted to 3,564,119 florins, representing, at the present rate of exchange, about $1,358,000. It is curious to note the large number of international messages as compared with those sent inland. Out of the total of over 6,000,000, 1,347,374 were telegrams transmitted from or to places abroad.

France.—At a recent meeting of the Paris town council two members suggested that the council should establish a municipal service of electric lighting throughout the whole of Paris, and they have asked for the appointment of a special committee, composed of members of the town council and professional engineers and electricians, for the purpose of reporting on the best method of carrying out this idea. The new police regulations regarding the installation of electric lighting in theatres and other public places, are viewed with great dissatisfaction by local electricians. They are extremely strict, and will tend to increase the cost and retard the progress of installation work. For instance, all lamps must be surrounded by wire netting (glow lamps not excepted), samples of all the conductors must be submitted, the plans of these installations have to be submitted to the prefect of police in triplicate, and the work must not be begun until permission has been given.

India.—Experiments are shortly to be made with a view to the introduction of the electric light into the railway carriages in India. Owing to the long distances to be traversed in India, night journeys are a necessity; in fact, by reason of the comparative coolness of the night traveling, many people prefer trains which run after dark.

Spain.—An enterprise contemplating the electric transmission of power on a very large scale is on foot in Spain. The undertaking is to utilize the water power of the river Turia to the extent of about 3,000 h. p. at a point, Chulilla, 35 miles from Valencia, and to deliver in that city about 1,500 h. p. for the use of manufacturers in the daytime and for electric lighting at night. From a notice in the *Electrician*, London, it appears that the Spanish promoters have prepared estimates of the outlay required, as well as of the revenues and expenses of the business. The estimated figures are substantially as follows:

Capital expenditure	$907,500	
Revenue from supply of power		$206,610
" " light		138,710
Gross revenue		$345,320
Expense of operation, including depreciation		87,300
Net revenue		$258,020

Or nearly 30 per cent. on capital outlay.

The promoters are said to be open to receive suggestions and plans for the electrical plant, as no particular system has yet been adopted.

NEW INCORPORATIONS.

The Fernwood Electric Light and Power Company, Fernwood, Ill. Capital stock, $15,000. Louis P. Scoville, and others, incorporators.

An electric light company has organized to establish a plant at Hanover, Pa. Estimated outlay, $16,000. Address F. A. Ziegler.

The Columbus Edison Electric Illuminating Company, Columbus, Ohio. Capital stock, $100,000. William C. Turner, and others, incorporators.

The Johnstown Electric Light and Power Company, Johnstown, N. Y. Capital stock, $20,000. Jacob P. Miller, and others, incorporators.

The Brush Electric Light and Power Company, Waverly, N. Y. Capital stock, $20,000. James A. Clark, and others, incorporators.

The Edison Electric Light and Power Company, Minneapolis, Minn. Capital stock, $4,000,000. A. F. Rockwell, and others, incorporators.

The Brooklyn Electric Light and Power Company, Brooklyn, N. Y. Capital stock, $100,000. Noah L. Cochen, and others, incorporators.

The Columbus Edison Electric Illuminating Co., of Columbus, O., with a capital of $100,000. Messrs. W. C. Turner, Wm. S. Ide, J. H. Collins, and others, are incorporators.

The Thomson-Houston Electric Light and Power Co., of Newton, Ia. Capital, $25,000, and the following officers: President, H. M. Vaughn; secretary and treasurer, C. H. Wilder.

The Peekskill Electric Light and Power Co. of Cortlandt, N. Y. Capital stock, $30,000. Messrs. Geo. V. Frost and Thos. D. Husted, of Peekskill, are the local parties interested.

Messrs. J. P. Miller, Chas. O. and Jas. H. Cross, A. J. Nellis, Jno. G. Ferris, and others, have organized the Johnstown Electric Light and Power Co., of Johnstown, N. Y., with an initial capital of $20,000

The Edison Light and Power Co., of La Crosse, Wis., has a capital stock of $150,000. Among those interested are G. Van Steenwyke, W. H. Holcomb and S. Y. Hyde.

The Dodge City Electric Light and Heating Co., Dodge City, Kan., has been incorporated by F. Gardner, and others, with a capital stock of $50,000.

Messrs. J. Monroe Shellenberger, Henry Lear, Alf. Pashall and others, are organizing the Doylestown Electric Light Co., at Doylestown.

The Edison Electric Illuminating Co., of Brooklyn, N. Y., has been incorporated, with a capital of $500,000. Messrs. Eugene

Digitized by Google

and Chas. E. Crowell, Wm. D. Sargent, Spenser Trask, and others, are incorporators.

The Pratt City Electric Light Co., of Pratt, Kan., has been incorporated, with a capital of $25,000.

The Hallowell Light and Power Co., Hallowell, Me., has been incorporated with a capital of $50,000. Emory A. Sanborn is president.

The Newburyport Electric Light and Power Co., of Newburyport, Mass., capital, $15,000. Messrs. Wm. E. Chase, W. A. Stiles, Wm. R. Johnson, and others, are incorporators.

The Brooklyn Electric Light and Power Co., of Brooklyn, N. Y. Capital stock, $100,000. Messrs. R. G. Phelps, Noah L. Cochen, Wm. H. Palmer, Jas. H. Hurst, and others, are incorporators.

The Idaho Electric Supply Co., of Hailey, Idaho, has been incorporated, and the following officers elected: President, Texas Angel; secretary and treasurer, S. C. John. Capital stock, $20,000.

The Georgetown Electric Co., Georgetown, Cal. Capital stock, $7,500. James E. Tucker, and others, incorporators.

The Peekskill Electric Light and Power Co., Cortlandt, N. Y. Capital stock, $30,000. George B. V. Furst, and others, incorporators.

The Mexico Electric Light and Power Co., Mexico, Mo. Capital stock, $10,000. J. F. Llewellyn, and others, incorporators.

The Capital Electric Light, Motor, and Gas Co., Boise City, Idaho Ter. Capital stock, $10,000. Wm. H. Nye, and others, incorporators.

The Standard Electric Co., New York city. Capital stock, $500,000. Frank Tach, and others, incorporators.

The Ticonderoga Electric Light and Power Co., Ticonderoga, N. Y. Capital stock, $16,000. George S. Clark, and others, incorporators.

The Gogebic Electric Light Co., Aurora, Ill. Capital stock, $30,000. John H. Pease, and others, incorporators.

The North New York Lighting Co., of New York city. Capital, $150,000. The corporators include Jordan L. Mott, Jr., Thos. N. Motley, Herman Clark, M. H. Cardoza, and others.

The Brush Electric Light and Power Co., of Waverly, N. Y. Capital, $20,000. Mr. James A. Clark can give all particulars.

MANUFACTURING AND TRADE NOTES.

The New York office of the American Electrical Works of Providence, R. I., has been removed to the new telephone building, 16 Cortlandt street, where Mr. Harry Hall, the New York agent, will henceforth be found.

The New York, Lake Erie and Western Railway has, within the last month, made a contract with the Union Switch and Signal Company, of Pittsburg, for a system of block signals and interlocking switches, with the Sykes attachment, which is to be completed by the middle of June at a cost of $60,000. The portion of the road to receive this attention is that on which there is an immense suburban travel, extending as far west as Turners, 49 miles from New York. The necessary equipment to fulfill the Erie contract will consist of 27 towers or signal stations situated at different points between New York and Turners, and at the following points, 10 in all, there will be a complete system of interlocking switches: East and west ends of the Bergen tunnel, Seamens, Hackensack drawbridge, New Jersey and New York Junction, Rutherford Junction, Ridgewood Junction, Sterling Junction and Southfield. Work will begin immediately, and it will require 200 men for this purpose.

High rents and taxes in New York are rapidly driving manufacturers to the near-by cities, and in a few weeks A. & F. Brown, manufacturers of pulleys, hangers and shafting, will have moved the principal portion of their works to Elizabeth, New Jersey. The machine shop of the old works on Lewis street, New York, which has been established there over 30 years, will be retained, but the remainder of the works will be leased for other business. Messrs. A. & F. Brown, of New York, will remove their office from 43 to 44 Park place on May 1st.

INVENTORS' RECORD.

Prepared expressly for THE ELECTRICIAN AND ELECTRICAL ENGINEER, *by* Pope, Edgecomb & Terry, *Solicitors of Patents for Electrical Inventions*, 11 *Wall Street, New York city.*

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From March 15 to April 12th, 1887 (inclusive).

Alarms and Signals:—*Electric Annunciator*, J. C. Kunkle, 360,447 and 360,448, April 5. *Annunciator and Shunt Circuit Therefor*, J. A. Barret, 360,266, March 29. *Fire Alarm*, A. Sewel, 359,694. *Electric Circuit for Telephones and Fire and Burglar Alarms*, S. Taussig, 359,824. *Electric Fire and Burglar Alarm*, same, 359,823, March 22. *Automatic Fire-Alarm System*, W. F. Singer, 360,824. *Electric Thermostat or Fire-Alarm*, same, 360,823, April 5. *Automatic Fire-Telegraph*, M. Martin, 360,968, April 12. *Combined Push-Button and Thermostat*, F. Keffer and J. A. McDowell, 359,260. *Electric Bell*, F. B. Wood, 359,309. *Police Telegraph System*, J. F. Mehren and W. Carroll, 359,575. *Druggist Alarm*, M. Toulmin, 359,581, March 15. *Municipal Signal Apparatus*, B. J. Noyes, 359,686, 359,687 and 359,688. *Individual Call for Municipal Telegraph System*, same, 359,689, March 22. *Burglar Alarm Clock*, C. E. Burnham, 360,338. *Electric Signal System*, C. Lambdin, 360,025. *Electric Indicator*, F. K. Fitch, 360,381, March 29. *Electric House-Bell*, E. G. Coleman, 360,660, April 5. *Hydrometer Alarm*, T. P. Whittier, 360,980. *Telegraphic Alarm Signal*, T. E. Mosher, 361,020. *Station Indicator*, W. D. Doremus, 361,146, April 12. *Lamp Post and Signal*, W. C. Smith, 360,252, March 29.

Clocks:—*Primary Electric Clock*, J. J. Abell and C. D. Gifford, 360,078. *Secondary Electric Clock*, W. B. Harvey, 360,092, March 29. *Electric Pendulum Clock*, A. L. Parcelle, 360,903, April 12.

Conductors, Insulators, Supports and Systems:—*Mode of Setting Telegraph Poles*, W. Murray, 359,622. *Electrical Conductor*, E. H. Johnson, 359,726. *Underground Conduit for Powerful Electric Currents*, G. B. Pennock, 359,738. *Insulator for Supporting and Holding Electric Wires*, H. Pennie, 359,812. *Terminal for Telegraph Lines or Cables*, W. H. Sawyer, 359,816. *Insulating Material*, C. M. Thompson, 359,825. *Lightning Rod Standard or Brace*, T. H. Patee and S. R. Lawshe, 359,940, March 22. *Conduit for Underground Conductors*, H. Loesner and M. De Bravura, 360,316. *Insulator*, W. F. Locke, 360,354, March 29. *Underground Railway and Pipe Subway*, B. F. Carpenter, 360,655. *Insulating and Protecting Electric Cables*, T. H. Dunham, 360,567, April 5. *Subway*, C. Scheidl, 361,086. *System of Supporting and Repairing Electric Conducting Wires, &c.*, H. Flad, 361,217, April 12.

Distribution:—*Electric Lighting System*, F. A. Cheney, 359,718. *Regulator for Electric Circuits*, J. A. Powers, 359,739, March 22. *System of Electric Distribution*, E. Thomson, 360,122 and 360,125. *Induction Coil*, O. T. Blathy, 360,198. *Automatic Electric Circuit Controller*, T. P. Conant, 360,375, March 29. *System of Electrical Distribution*, F. Van Rysselberghe, 360,492. *Electric Lighting System*, J. A. Powers, 360,538, April 5.

Dynamos and Motors:—*Dynamo-Electric Machine*, N. Tesla, 359,748; R. J. Sheehy, 359,894, March 22; H. E. Walter and C. Batchelor, 360,258 and 360,259, March 29. *Regulator for Dynamo-Electric Machines*, C. L. Buckingham, 359,770, March 22. *Armature for Dynamo-Electric Machines*, W. A. Leipner, 360,030, March 29. *Electric Motor*, E. P. Clark, 359,429, March 15; F. E. Fisher, 360,216, March 29; W. Baxter, Jr., 361,115. *Horizontal Governor for Electric Motors*, same, 361,116. *Journal-Bearing for Electric Motors*, same, 361,117, April 12.

Galvanic Batteries:—*Electric Battery*, K. Pollak, 359,690. *Battery Zinc*, J. Beattie, Jr., 359,835, March 22. *Galvanic Battery*, P. Jablochkoff, 360,158. *Galvanic Battery Solution*, W. P. Kookogey, 360,024, March 29. *Connection for Carbon Elements in Galvanic Batteries*, same, 360,532, April 5. *Cabinet Battery*, H. E. Waite, 360,934. *Solution for Galvanic Batteries*, D. H. Fitch, 361,004, April 12.

Ignition:—*Electric Igniter for Gas Engines*, N. C. Bassett, 359,552, March 15. *Electric Gas Burner*, C. W. Holtzer, 360,696, April 5.

Lamps and Appurtenances:—*Electric Lamp*, C. Seel, 359,328, March 15. *Electric Arc Lamp*, L. Hanson, 360,151; J. Tregoning, 360,254; W. A. Crowdus and H. M. Sutton, 360,377, March 29; C. F. Cooke, 360,662, April 5. *Electric Lamp and Socket*, C. G. Perkins, 360,244. *Reflector for Electric Lights*, W. W. Downing and A. B. Upham, 360,002. *Apparatus for Suspending Electric Lights*, G. P. Nichols and M. Coombs, Jr., 360,040, March 29. *Cellular Furnace for Baking Carbons*, J. Hill, 359,866. *Electric Lamp Frame*, T. H. Brady, 359,916, March 22. *Mercurial Pump Exhausting Apparatus*, W. Maxwell and T. V. Hughes, 361,174, April 12.

Measurement:—*Combined Volt and Ampere Meter*, R. Macrae, 359,619, March 22.

Medical and Surgical:—*Cautery Electrode and Shield*, D. H. Goodwille, 359,506, March 15. *Electric Sole*, F. B. Wallis, 360,127, March 29. *Electro-Cautery Instrument for Use in Surgery*, D. H. Goodwille, 360,429, April 5.

Metallurgy:—*Apparatus for Separating Metals from Ores and Alloys*, H. R. Cassel, 360,852, April 12.

Miscellaneous:—*Apparatus for Testing Electric Circuits*, A. D. Wheeler, 359,338. *Fluid-Pressure Motor*, G. Westinghouse, Jr., 359,303. *Electric Torpedo Boat*, H. M. Bennett, 359,313. *Electrical Apparatus for Regulating Temperature*, C. W. Johnson, 359,392. *Carrier for Electro-Pneumatic Despatch-Tube Systems*, J. F. McLaughlin, 359,456. *Electrical Pneumatic Despatch-Tube*, same, 359,540, March 15. *Apparatus for Controlling Low Pressures*, M. W. Grovesteen, 359,673. *Automatic Feed for Printing Presses*, J. A. Wetmore, 359,752. *Electrical Synchronal Escapement*, J. F. McLaughlin, 359,805. *Aerial Photographic Apparatus*, M. J. Steffens, 359,902. *Process of Curing India Rubber*, C. M. Thompson and O. Lugo, 359,907. *Coupling for Electric Conductors*, F. G. Plume, 359,982, March 22. *Electro-Magnetic Cut-Off*, E. Thomson, 360,123. *Automatic Cut-Off*, same, 360,124. *Electrical Apparatus for Heating and Cooling Buildings*, E. H. Johnson, 360,223. *Watchman's Time-Recorder*, E. J. Colby, 359,999. *Electric Furnace*, E. H. and A. H. Cowles, 360,144, March 29. *Apparatus for Re-Cutting Files*, J. E. Emley, 360,517. *Target Trap*, J. B. Bennett and F. W. Samuels, 360,647. *Connection-Hanger for Electrotyping Apparatus*, O. S. Fertig, 360,672. *Vapor-Bath*, E. Hosford, 360,773. *Electric-Instrument Protector*, I. H. Farnham, 360,570, April 5. *Electrical Apparatus for Separating Metallic Particles from Paper-Pulp*, C. H. Atkins, 360,842. *System of Indicating Time by Electric Lights*, P. B. Delany, 360,862. *Electric Wire Coupling*, R. Solano, 360,925. *Holder for Metal Articles*, H. D. Winton, 361,248. *Process of and Apparatus for Tanning by Electricity*, E. Worms and J. Balé, 361,249, April 12.

Railways and Appliances:—*Electric Railway*, I. W. Heysinger, 359,607, March 22. *Railway Signal*, M. W. Long, 359,512, March 15; G. H. Wright, 360,077. *Electric Railway Signal*, J. McM. Scott, 360,175, March 29. *Railway Electric Signaling Apparatus*, G. Westinghouse, Jr., 360,638, April 5. *Automatic Electric Air-Brake*, J. F. Carpenter, 359,593, March 22. *Electric Car Brake*, E. A. Sperry, 360,060. *Power-Brake*, R. Solano, 360,179, March 29. *Railroad Brake*, C. Selden, 361,090; *Automatic Car-Brake*, same, 361,089, April 12. *Railway-Crossing Alarm*, S. P. Van Nort, 359,371, March 15. *Railway Car Telegraphy*, J. A. Barrett, 359,990, March 29.

Secondary Batteries:—*Secondary Battery*, A. V. Meserole, 359,877; W. Main, 359,934, March 22. *Positive-Pole Plate for Secondary Batteries or Accumulators*, S. Farbaky and S. Schenek, 359,248, March 15. *Process of Preparing Secondary Battery Plates*, A. V. Meserole, 359,876. *Charging and Discharging Secondary Batteries*, E. T. Starr, 359,900; *Mechanism for Charging Secondary Batteries*, same, 359,901, March 22.

Telegraphs:—*Telegraphy*, W. T. Barnard, 360,844; A. M. A. Beale, 360,986, and 360,987 April 12. *Quadruplex Telegraphy*, F. W. Jones, 360,528, April 5. *Multiple Telegraph System*, A. M. A. Beale, 360,988. *Automatic Printing-Telegraph*, C. G. Burke, 360,994 and 360,995, April 12. See *Railways*, last item.

Telephones, Systems and Apparatus:—*Telephone*, H. E. Waite, 360,068, March 29. *Telephone Receiver*, J. H. Tabony, 360,626, April 5. *Telephone Transmitter*, W. Burnley, 361,047. *Telephoning*, J. W. Bonta, 361,124, April 12. *Return Attachment for Telephone Toll-Collectors*, C. Wittenberg, 359,306; *Telephone Register*, same, 359,307 and 359,308. *Telephone Switch*, C. A. Hitchcock, 359,356. *Telephone Cabinet*, C. B. Balloch, 359,492, March 15. *Telephone Signal*, C. R. Swain, 359,984, March 22. *Electro-Acoustic Apparatus*, A. A. Knudson, 360,308. *Mechanical Telephone*, C. M. Radford, 360,362, March 29. *Toll-Collecting Apparatus for Public Telephone Stations*, J. H. Tabony, 359,747, March 22.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of the* ELECTRICAL PUBLISHING CO. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICIAN AND ELECTRICAL ENGINEER, 115 *Nassau Street, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

NEW YORK, JUNE, 1887.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE founders and members of the American Institute of Electrical Engineers, have cause for extreme gratification in the work of the Annual and General Meetings, May 17th and 18th. Their gratification will be shared by all interested in any way in the development of electrical science or of the useful arts based upon it. The columns of our present issue are largely devoted to the report of the meetings, and contain all of the papers read at the general meeting, on Wednesday, the 18th. Their perusal will make clear to our readers the reasons for satisfaction to which we have alluded. The attendance as well as the character of the papers read and of the discussions following, well attest the success of the Institute in drawing together the labors of scientific investigators and practical workers in the field of electric engineering, and illustrate afresh the close interdependence of research in the laboratory and practice in factory or afield, in developing improved methods and results. The astounding rapidity with which electricity has reached out for, taken and held new fields, is a significant, perhaps the most striking, feature in the general advance in the arts of utility so characteristic of the present period. That the American Institute of Electrical Engineers will maintain its part of the work, is shown by its steadily improving record during the three years of its existence; that it will put itself on a firmer basis and augment its usefulness may be confidently expected from the movement so promisingly initiated at the recent meeting towards securing permanent quarters, a home of its own, with an assembly room, sufficient space for a library, reading room, museum, and such other uses as the needs of the Institute will require. The project met with such cordial response, and was so generally supported that its success may be taken as assured. We print elsewhere a list of subscriptions to the house fund up to May 28th, amounting to $3,950, a most encouraging beginning. The Council of the Institute took the matter up energetically at a special meeting May 24th, appointing a special committee to carry on the work. The Institute did well at the annual meeting, in electing Mr. T. Commerford Martin, president. It is not too much to say that no one has been more deeply interested in the success of the Institute, nor more active and efficient in its work. We expect to be able to congratulate Mr. Martin upon including in his term the accomplishment of the Institute's undertaking, so hopefully begun, to provide itself a habitation.

ELECTRICITY FOR STREET RAILWAYS.

IT sometimes happens that a person unfamiliar with optical apparatus is best able to appreciate the magnifying power of a telescope by looking at familiar objects through its larger end, and not infrequently the true conditions of other problems may be best apprehended by viewing them inversely. Applying this method to a question of great practical importance just now exciting public interest, let us suppose a manufacturing establishment situated in the heart of a city like New York, where real estate is held at a high value, in which 150 machines each requiring 10 mechanical horse-power are driven by the usual equipment of steam engines and boilers. Now, let us suppose further that the New York State Legislature, in the exercise of the intelligent discretion which that august body invariably applies to the regulation of the internal affairs of the metropolis, should decree on and after a certain date "it shall not be lawful to operate machinery by steam or any other power than horse-power within the limits of said city," so that it would become necessary for the proprietors of the establishment to purchase a sufficient number of animals to supply 1,500 h. p. continuously, together with the necessary additional real estate in the immediate vicinity, whereon to erect buildings and furnish stable accommodations for the few thousand head of live stock required, and to add the cost of provender, attendance, replacement, etc. We imagine that the parties concerned would regard themselves as extremely fortunate if the cost of power under the new conditions proved to be less than five or six times as much as before. Yet the situation we have pictured, does not materially exaggerate the existing condition of affairs in respect to city transportation. A single street railway line in New York has in service about 350 cars and 2,000 horses. Not less than 1,500 h. p. must be constantly employed in the movement of the traffic, yet it would probably be difficult to convince the managers of this or any similarly situated surface railroad company that the whole line might be operated by a central steam plant and electric motors, at something like one-fourth the cost, for power, of the existing system. The paper of Mr. T. C. Martin, read at the

Digitized by Google

recent annual meeting of the electrical engineers, showed conclusively that so far as the use of electric power on small roads with light traffic is concerned, the domain of experiment has already been passed. Electric traction has become a settled fact, and from present indications, nothing can be more certain than that the smaller street railroad systems of the United States will adopt the new method as rapidly as the required machinery can be constructed and applied. In the case of lines in larger cities with heavier traffic, a similar result may be looked for at no distant day. No valid reason can be adduced why the electric system may not be applied to the more important lines with even greater proportionate economy than has been the case with small roads. It is probable that the only serious obstacle to the change will be the spirit of caution and conservatism naturally inherent in the minds of the managers of corporations having thousands and even millions of dollars invested in horse-power plant, which will lead them to ponder long and carefully before committing themselves to an innovation so radical, and necessarily accompanied with so large an expenditure. Nevertheless the advantages of the electric system in point of economy and of public convenience must ultimately prove so controlling that it hardly seems probable that even in such cases the inevitable change will be long delayed.

Mr. Martin's summary, which we print in another column, shows that there are now running in this country 11 electric railways, equipped with 68 motors and motor cars, and that a much larger number are either under contract or in course of construction. The systems of electric distribution from a central station both by conductors and by accumulators have proved successful in practice, and it is difficult to imagine any difficulties of operation which cannot be surmounted by one or the other of these methods or by a combination of the two. Investigations and comparisons of the different methods of electrical propulsion are being made by some of the largest street railway companies in the country, and such investigations, can have, we are confident, but one result.

LET THIS BE A WARNING.

On the morning of May 27th, the City of New York had an exceedingly narrow escape from the fate which was precipitated upon a sister metropolis by the ill-timed kick of Mrs. O'Leary's cow. A disastrous conflagration broke out in the car-house and stables of the Belt Line railway, which in a brief space of time consumed not only the immense building, but nearly the entire equipment of the road, including 1,185 horses, 145 cars, and a vast quantity of supplies, involving a total loss of over three-quarters of a million dollars. The neighborhood was thickly built up with flimsy brick and frame structures, twenty-five or more of which succumbed to the flames so quickly, that the occupants with difficulty escaped with their lives. For a time the fire was wholly beyond the control of the department, and had there been, as frequently happens at this time of year, a north-westerly wind from the river, the greater portion of New York city would inevitably have been swept from the face of the earth. But there still remain half a dozen more gigantic tinder-boxes of similar character and construction, every one of which is certainly destined sooner or later to meet with the same fate. These vast aggregations of combustible material constitute a perpetual menace to the safety of every building in the city, and it is high time that stringent measures were taken to abolish them. The outcry which has been kept up by interested parties against the comparatively harmless telegraph wires appears somewhat ludicrous, when we consider how uncomplainingly our citizens endure the continual blockade of their sidewalks by skids, merchandise and peanut-stands, and of their streets by endless rows of trucks and wagons belonging to Jerseymen and Long Islanders; and above all the nightly danger of being cremated in their beds by the admirably devised fire-traps of the horse-railroad companies. With the cable and more especially the electric systems of transport at their disposal, the erection by these corporations of any more such structures in a crowded city like New York, is little less than criminal, and ought not to be tolerated for a moment. The losses incurred in this one fire would more than cover the cost of changing the entire equipment of the Belt Line to an electric system. We trust that this disaster will at least have the good result of compelling serious attention to the improved methods of transportation which modern science has developed.

INSTITUTE NOTES.

The interesting character of the May meeting of the Institute of Electrical Engineers, together with the hearty inauguration of a plan to secure a permanent location in a house of its own, have stimulated the desire for membership remarkably. Some 30 new members have been added since May 17th. In another column we print the full list of officers for 1886-87, and of the membership as it stood May 25th.

The New York Electrical Society (now the electrical section of the American Institute) having undertaken an Electrical Exhibition to be held next autumn (Sept. 28th–Dec. 3d) in connection with the annual exhibition of the American Institute, the Council of the Institute of Electrical Engineers has pledged its hearty interest and support to the project.

The exhibition is intended to include all applications of electricity, and will afford an excellent opportunity to inventors and manufacturers. Information will be furnished by Mr. J. M. Pendleton, President of the society, 49 Broadway; Mr. J. Wetzler, Secretary, 175 Potter Building, or Mr. C. W. Hull, Superintendent of the American Institute, Clinton Hall.

In aid of the House Fund, the Council of the Institute has decided to arrange a Course of Lectures on electrical subjects, to be delivered in a large hall during the fall and early winter. It is intended to have the lectures of a somewhat popular character, though not wanting in sound scientific foundation. It is believed that general interest in electrical arts is so rapidly increasing as to insure popular support to such a course. Gentlemen well known for their ability and attainments will be invited to lecture; several having already promised their services; among them Prof. Elihu Thomson, Mr. T. D. Lockwood and Mr. E. H. Johnson.

It is thought probable that a way will be found, through the joint efforts of the Institute of Electrical Engineers and the New York Electrical Society, to combine the Electrical Exhibition and the Course of Lectures, thus increasing the attractiveness and usefulness of both.

ARTICLES.

NOVEL PHENOMENA OF ALTERNATING CURRENTS.[1]

BY ELIHU THOMSON.

The actions produced and producible by the agency of alternating currents of considerable energy, are assuming greater importance in the electric arts. I mean, of course, by the term alternating currents, currents of electricity reversed at frequent intervals, so that a positive flow is succeeded by a negative flow, and that again by a positive flow, such reversals occurring many times in a second, so that the curve of current or of electromotive-force will, if plotted, be a wave line, the amplitude of which is the arithmetical sum of the positive and negative maxima of current or electromotive-force, as the case may be, while a horizontal middle line joins the zero points of current or electromotive-force.

It is well known that such a current passing in a coil or conductor laid parallel with or in inductive relation to a second coil or conductor, will induce in the second conductor, if on open circuit, alternating electromotive forces, and that if its terminals be closed or joined, alternating currents of the same rhythm, period or pitch, will circulate in the second conductor. This is the action occurring in any induction coil whose primary wire is traversed by alternating currents, and whose secondary wire is closed either upon itself directly or through a resistance. What I desire to draw attention to in the present paper are the mechanical actions of attraction and repulsion which will be exhibited between the two conductors, and the novel results which may be obtained by modifications in the relative dispositions of the two conductors.

In 1884, while preparing for the International Electrical Exhibition at Philadelphia, we had occasion to construct a large electro-magnet, the cores of which were about six inches in diameter and about twenty inches long. They were made of bundles of iron rod of about $\frac{1}{4}$ inch diameter. When complete the magnet was energized by the current of a dynamo giving continuous currents, and it exhibited

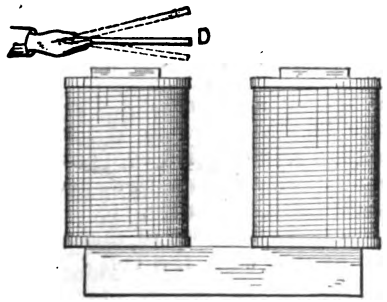

FIGURE 1.

the usual powerful magnetic effects. It was found also that a disc of sheet copper, of about $\frac{1}{16}$ inch thickness and 10 inches in diameter, if dropped flat against a pole of the magnet, would settle down softly upon it, being retarded by the development of currents in the disc due to its movement in a strong magnetic field, and which currents were of opposite direction to those in the coils of the magnet. In fact, it was impossible to strike the magnet pole a sharp blow with the disc even when the attempt was made by holding one edge of the disc in the hand and bringing it down forcibly towards the magnet. In attempting to raise the disc quickly off the pole, a similar but opposite action of resistance to movement took place, showing the development of currents in the same direction to those in the coils of the magnet, and which currents, of course, would cause attraction as a result.

The experiment was, however, varied, as in figure 1. The disc D was held over the magnet pole, as shown, and the current in the magnet coils cut off by shunting them. There was felt an attraction of the disc or a dip toward the pole. The current was then put on by opening the shunting switch and a repulsive action or lift of the disc was felt. The actions just described are what would be expected in such a case, for when attraction took place, currents had been induced in the disc D in the same direction as those in the magnet coils beneath it, and when repulsion took place the induced current in the disc was of opposite character or direction to that in the coils.

Now let us imagine the current in the magnet coils to be not only cut off, but reversed back and forth. For the reasons just given we will find that the disc D is attracted and repelled alternately, for, whenever the currents induced in it are of the same direction with those in the inducing, or magnet coil, attraction will ensue, and when they are opposite in direction, repulsion will be produced. Moreover, the repulsion will be produced when the current in the magnet coil is rising to a maximum in either direction, and attraction will be the result when the current of either direction is falling to zero, since in the former case opposite currents are induced in the disc D in accordance with well-known laws; and in the latter case currents of the same direction will exist in the disc D and the magnet coil. The disc might, of course, be replaced by a ring of copper or other good conductor, or by a closed coil of bare or insulated wire, or by a series of discs, rings or coils superposed, and the results would be the same. Thus far, indeed, we have nothing of a particularly novel character, and, doubtless, other experimenters have made very similar experiments and noted similar results to those described.

The account just given of the effects produced by alternating currents, while true, is not the whole truth, and just here we may supplement it by the following theorems:

An alternating current circuit or coil repels and attracts a closed circuit or coil placed in direct or magnetic inductive relation therewith, but the repulsive effect is in excess of the attractive effect.

When the closed circuit or coil is so placed, and is of such low resistance metal that a comparatively large current can circulate as an induced current, so as to be subject to a large self-induction, the repulsive far exceeds the attractive effort.

For want of a better name I shall call this excess of repulsive effect the "electro-inductive repulsion" of the coils or circuits.

This preponderating repulsive effect may be utilized or may show its presence by producing movement or pressure in a given direction, by producing angular deflection as of a pivoted body, or by producing continuous rotation with a properly organized structure. Some of the simple devices realizing the conditions I will now describe.

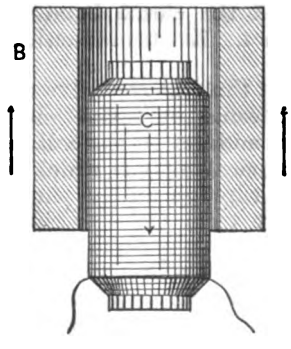

FIGURE 2.

In figure 2 C is a coil traversed by alternating currents, B is a copper case or tube surrounding it, but not

1. Read before the American Institute of Electrical Engineers, May 18th, 1887.

Digitized by Google

exactly over its centre. The copper tube B is fairly massive and is the seat of heavy induced currents. There is a preponderance of repulsive action tending to force the two conductors apart in an axial line. The part B may be replaced by concentric tubes slid one in the other, or by a pile of flat rings, or by a closed coil of coarse or fine wire insulated or not. If the coil C, or primary coil, is provided with an iron core such as a bundle of fine iron wires, the effects are greatly increased in intensity and the repulsion with a strong primary current may become quite vigorous, many pounds of thrust being producible by apparatus of quite moderate size.

The forms and relations of the two parts C and B may be greatly modified with the general result of a preponderance of repulsive action when the alternating currents circulate.

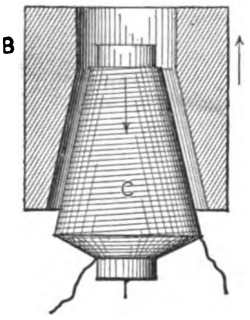

FIGURE 3.

Figure 3 shows the part B of an internally tapered or coned form, and C of an externally coned form, wound on an iron wire bundle I. The action in figure 2 may be said to be analogous to that of a plain solenoid with its core, except that repulsion and not attraction, is produced, while that of figure 3 is more like the action of tapered or conically wound solenoids and taper cores. Of course it is unnecessary that both be tapered. The effect of such shaping is simply to modify the range of action and the amount of repulsive effort existing at different parts of the range.

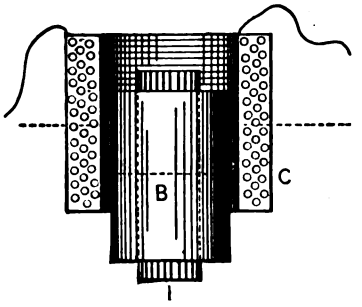

FIGURE 4.

In figure 4 the arrangement is modified so that the coil C is outside, and the closed band or circuit B inside and around the core I. Electro-inductive repulsion is produced as before.

It will be evident that the repulsive actions will not be mechanically manifested by axial movement or effort, when the electrical middles of the coils or circuits are coincident. In cylindrical coils in which the current is uniformly distributed through all the parts of the conductor section, what I here term the electrical middle, or the centre of gravity of the ampere turns of the coils, will be the plane at right angles to its axis at its middle, that of B and C in figure 4 being indicated by a dotted line. To repeat, then, when the centres or centre planes of the conductors, figure 4, coincide, no indication of electro-inductive repulsion is given, because it is mutually balanced in all directions; but when the coils are displaced, a repulsion is manifested, which reaches a maximum at a position depending on the peculiarities of proportion and distribution of current at any time in the two circuits or conductors.

It is not my purpose now to discuss the ways of determining the distribution of currents and mechanical effects, as that would extend the present paper much beyond its intended limit. The forms and relative arrangement of the two conductors may be greatly varied. In figure 5

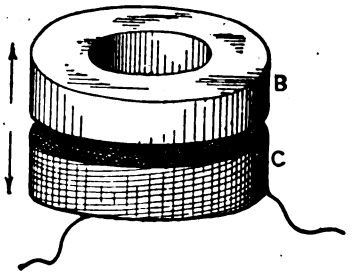

FIGURE 5.

the parts are of equal diameter, one, B, being a closed ring, and the other, C, being an annular coil placed parallel thereto, and an iron core or wire bundle placed in the common axis of the two coils increases the repulsive action. B may be simply a disc or plate of any form without greatly affecting the nature of the action produced. It may also be composed of a pile of copper washers or a coil of wire, as before indicated.

An arrangement of parts somewhat analogous to that of a horseshoe electro-magnet and armature is shown in

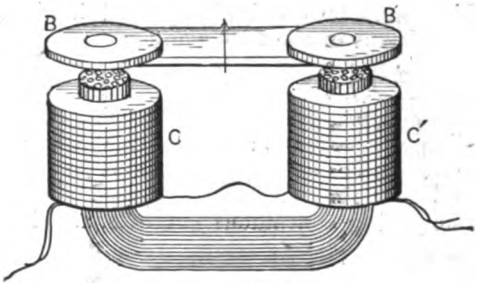

FIGURE 6.

figure 6. The alternating current coils C C′ are wound upon an iron wire bundle bent into U-form, and opposite its poles is placed a pair of thick copper discs B B′, which are attracted and repelled, but with an access of repulsion depending on their form, thickness, etc.

If the iron core takes the form of that shown by I I, figure 7, such as a cut ring with the coil C wound thereon,

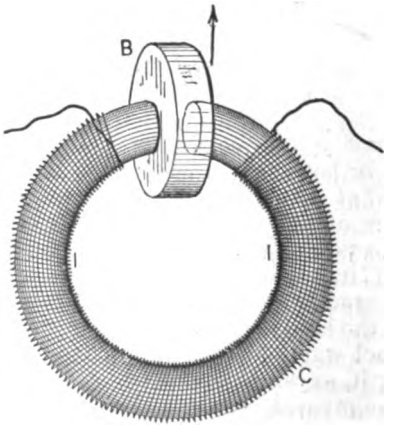

FIGURE 7.

the insertion of a heavy copper plate B into the slot or divided portion of the ring will be opposed by a repulsive effort when alternating currents pass in C. This was the

Digitized by Google

first form of device in which I noticed the phenomenon of repulsive preponderance, in question. The tendency is to thrust the plate B out of the slot in the ring excepting only when its centre is coincident with the magnetic axis joining the poles of the ring between which B is placed.

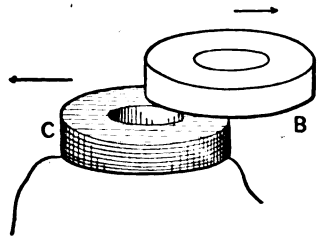

FIGURE 8.

If the axis of the conductors, figure 5, are not coincident but displaced as in figure 8, then, besides a simple repulsion apart, there is a lateral component or tendency as indicated by the arrows. Akin to this is the experiment illustrated in figure 9. Here the closed conductor B is

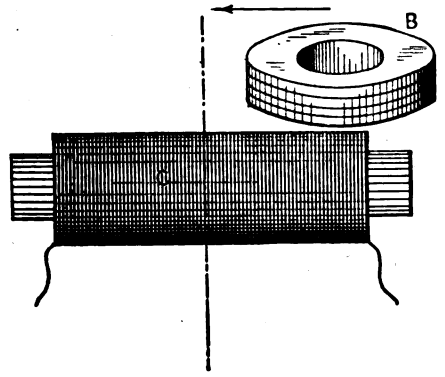

FIGURE 9.

placed with its plane at right angles to that of C, wound on a wire bundle. The part B tends to move toward the centre of the coil C, so that its axis will be in the middle plane of C, transverse to the core, as indicated by the dotted line. This leads us at once to another class of actions, *i. e.*, deflective actions.

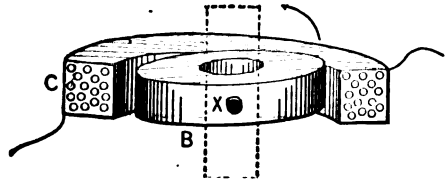

FIGURE 10.

When one of the conductors, as B, figure 10, composed of a disc, or better, of a pile of thin copper discs, or of a closed coil of wire, is mounted on an axis X, transverse to the axis of coil C, through which coil the alternating current passes, a deflection of B to the position indicated by dotted lines will take place, unless the plane of B is at the start exactly coincident with that of C. If slightly inclined at the start, deflection will be caused as stated. It matters not whether the coil C incloses the part B or be inclosed by it, or whether the coil C be pivoted and B fixed, or both be pivoted. In figure 11 the coil C surrounds an iron wire core, I and B is pivoted above it, as shown. It is deflected, as before, to the position indicated in dotted lines.

It is important to remark here that, in cases where deflection is to be obtained, as in figures 10 and 11, B had best be made of a pile of thin washers or a closed coil of insulated wire instead of a solid ring. This avoids the lessening of effect which would come from the induction of currents in the ring B in other directions than parallel to its circumference.

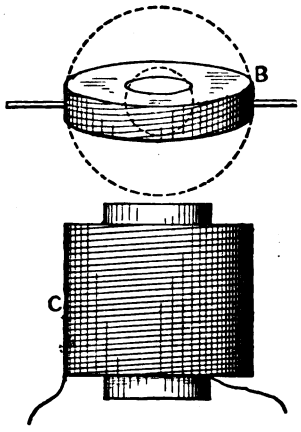

FIGURE 11.

We will now turn our attention to the explanation of the actions exhibited, and afterwards refer to their possible applications. It may be stated as certainly true that were the induced currents in the closed conductor unaffected by any self-induction, the only phenomena exhibited would be alternate equal attractions and repulsions, because currents would be induced in opposite directions to that of the primary current when the latter current was changing from zero to maximum, positive or negative current, so producing repulsion; and would be induced in the same direction when changing from maximum positive or negative value to zero, so producing attraction.

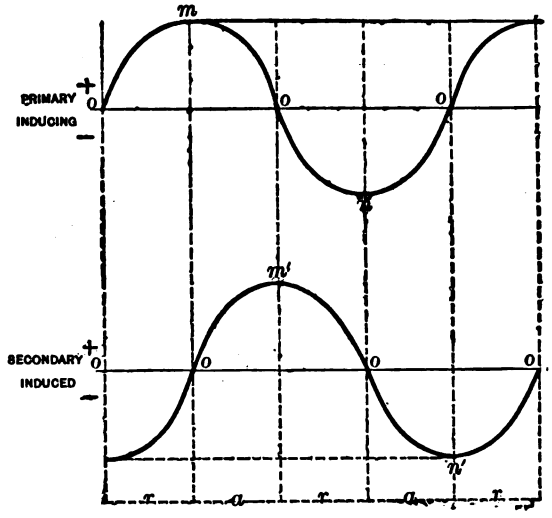

FIGURE 12.

This condition can be illustrated by a diagram, figure 12. Here the lines of zero current are the horizontal straight lines. The wavy lines represent the variations of current strength in each conductor, the current in one direction being indicated by that portion of the curve above the zero line, and in the other direction by that portion below it. The vertical dotted lines simply mark off corresponding portions of phase or succession of times.

Here it will be seen that in the positive primary current descending from *m*, its maximum to the zero line, the secondary current has risen from its zero to *m* , its maximum. Attraction will therefore ensue. for the currents are in the same direction in the two conductors. When the primary current increases from zero to its negative maximum *n*, the positive current in the secondary closed circuit

Digitized by Google

will be decreasing from m^1, its positive maximum to zero; but as the currents are in opposite directions, repulsion will occur. These actions of attraction and repulsion will be reproduced continually, there being a repulsion, then an attraction, then a repulsion, and again an attraction, during one complete wave of the primary current. The letters *r*, *a*, at the foot of the diagram, figure 12, indicate this succession.

In reality, however, the effects of self-induction in causing a lag shift, or retardation of phase in the secondary current, will considerably modify the results, and especially so when the secondary conductor is constructed so as to give to such self-induction a large value. In other words, the maxima of the primary or inducing current will no longer be found coincident with the zero points of the secondary currents. The effect will be the same as if the line representing the wave of the secondary current in figure 12 had been shifted forward to a greater or less extent. This is indicated in diagram, figure 13. It gives

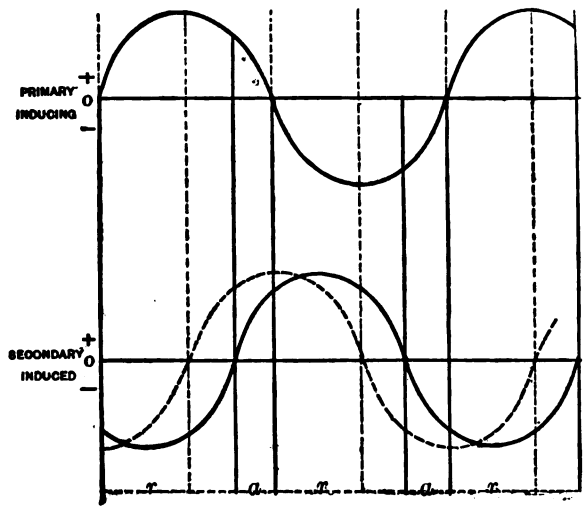

FIGURE 13.

doubtless an exaggerated view of the action, though from the effects of repulsion which I have produced I should say it is by no means an unrealizable condition.

It will be noticed that the period during which the currents are opposite, and during which repulsion can take place, is lengthened at the expense of the period during which the currents are in the same direction for attractive action. These differing periods are marked *r*, *a*, etc., or the period during which *repulsion* exists is from the zero of the primary or inducing current to the succeeding zero of the secondary or induced current; and the period during which *attraction* exists is from the zero of the induced current to the zero of inducing current.

But far more important still in giving prominence to the repulsive effect than this difference of effective period, is the fact that during the period of repulsion both the inducing and induced currents have their greatest values, while during the period of attraction the currents are of small amounts comparatively. This condition may be otherwise expressed by saying that the period during which repulsion occurs includes all the maxima of current, while the period of attraction includes no maxima. There is then a *repulsion due to the summative effects of strong opposite currents* for a *lengthened period*, against an *attraction* due to the summative effects of *weak currents* of the *same direction* during a *shortened period*, the resultant effect being a greatly *preponderating* repulsion.

It is now not difficult to understand all the actions before described as obtained with the varied relations of coils, magnetic fields and closed circuits. It will be easily understood, also, that an alternating magnetic field is in all respects the same as an alternating current coil in producing repulsion on the closed conductor, because the repulsions between the two conductors are the result of magnetic repulsions arising from opposing fields produced by the coils when the currents are of opposite directions in them.

Thus far I have applied the repulsive action described in the construction of alternating current indicators, alternating current arc lamps, regulating devices for alternating currents, and to rotary motors for such currents. For current indicators, a pivoted or suspended copper band or ring composed of thin washers piled together and insulated from one another and made to carry a pointer or index, has been placed in the axis of a coil conveying alternating currents whose amount or potential is to be indicated. Gravity or a spring is used to bring the index to the zero of a divided scale, at which time the plane of the copper ring or band makes an angle of, say, 15 degrees to 20 degrees with the plane of the coil. This angle is increased by deflection more or less great, according to the current traversing the coil. The instrument can be calibrated for set conditions of use. Time would not permit of a full description of these arrangements as made up to the present.

In arc lamps the magnet for forming the arc can be composed of a closed conductor, a coil for the passage of current, and an iron wire core. The repulsive action upon the closed conductor lifts and regulates the carbons in much the same manner that electro-magnets do when continuous currents are used. The electro-inductive repulsive action has also been applied to regulating devices for alternating currents, with the details of which I cannot now deal.

For the construction of an alternating current motor which can be started from a state of rest the principle has also been applied, and it may here be remarked, that a number of designs of such motors are practicable.

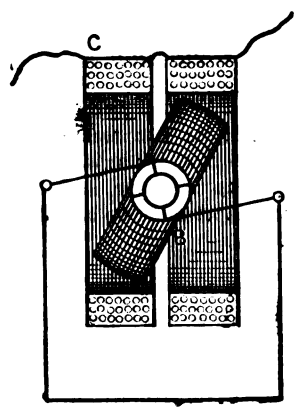

FIGURE 14.

One of the simplest is as follows: The coils C, figure 14, are traversed by an alternating current and are placed over a coil B, mounted upon a horizontal axis, transverse to the axis of the coils C. The terminals of the coils B, which is wound with insulated wire, are carried to a commutator, the brushes being connected by a wire as indicated. The commutator is so constructed as to keep the coil B on short circuit from the position of coincidence with the plane of C, to the position where the plane of B is at right angles to that of C; and to keep the coil B open circuited from the right angled position or thereabouts to the position of parallel or coincident planes. The deflective repulsion exhibited by B will, when its circuit is completed by the commutator and brushes, as described, act to place its plane at right angles to that of C, but being then open-circuited its momentum carries it to the position just past parallelism, at which moment it is again short-circuited, and so on. It is capable of very rapid rotation, but its

Digitized by Google

energy is small. I have, however, extended the principle to the construction of more complete apparatus. One form has its revolving portion or armature composed of a number of sheet iron discs wound as usual with three coils crossing near the shaft. The commutator is arranged to short-circuit each of these coils in succession, and twice in a revolution, and for a period of 90 degrees of rotation each. The field coils surround the armature and there is a laminated iron field structure completing the magnetic circuit. I may say here that surrounding the armature of a dynamo by the field coils, though very recently put forth as a new departure, was described in various Thomson-Houston patents, and to a certain extent all Thomson-Houston machines embody this feature.

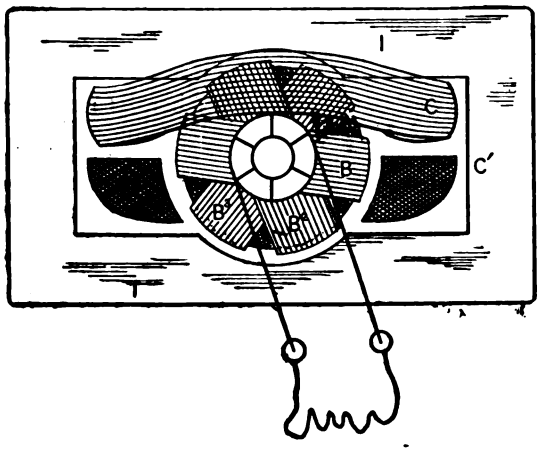

FIGURE 15.

Figs. 15 and 16 will give an idea of the construction of the motor referred to. C C¹ are the field coils or inducing coils which alone are put into the alternating current circuit. I I is a mass of laminated iron, in the interior of which the armature revolves, with its three coils B, B', B² wound on a core of sheet-iron discs. The commutator short-circuits the armature coils in succession in the proper positions to utilize the repulsive effect set up by the currents which are induced in them by the alternations in the field coils. The motor has no dead point and will start from a state of rest and give out considerable power, but with what economy is not yet known.

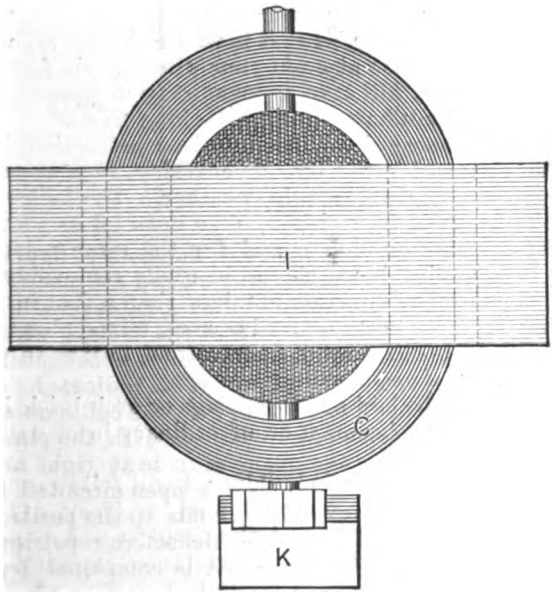

FIGURE 16.

A curious property of the machine is that at a certain speed, depending on the rapidity of the alternations in the coil C, a continuous current passes from one commutator brush to the other, and it will energize electro-magnets and perform other actions of direct currents. Here we have, then, a means of inducing direct currents from alternating currents. To control the speed and keep it at that required for the purpose, we have only to properly gear the motor to another of the ordinary type for alternating currents, namely, an alternating current dynamo used as a motor. The charging of storage batteries would not be difficult with such a machine, even from an alternating current line, though the losses might be considerable.

CENTRAL STATION CONSTRUCTION.[1]

BY J. A. POWERS.

THERE are two ways of constructing a central station for electric lighting, each of which has its special object. They may be defined as the speculative and the investment plans. The first has as its legitimate, or rather illegitimate end, the sale of the plant to some unfortunate, perhaps unwilling capitalist, by fair means or foul. We may consider as fair means the not uncommon method of selling a small portion of the stock, perhaps just enough to pay for the apparatus, on the strength of a showy exhibition in the hands of an expert, who uses all the tricks of the trade to persuade his lambs that his system will produce double the light with half the power of any other, and the other customary arguments.

The foul means is the border ruffian money-or-your-life policy, which enters a territory already sufficiently well served, not for fair competition, but to make money by being bought out.

The electric light business is rapidly emerging from the border ruffian and blackmailing stage, and, as we may shortly expect these methods to be relegated to their proper realm with other things dead and dishonorable, with the growth of popular knowledge of electrical matters, we will leave them, and proceed to the more legitimate methods, which I hope you will all pursue.

"The fool doth think he is wise, but the wise man knows himself to be a fool," said the master of all writers, and that I may be saved entering the first class in your presence, I here confess to many and grievous mistakes in our own central station construction, to which this paper owes its being, for that I may hope to save some of you part of my errors is my only excuse for appearing before you.

Let us, then, drop speculation as a thing of the past in our business, and make our object the construction of such work as shall produce, in the sober judgment of every business man among you, the best results in economy of labor, supplies and power, with the least expenditure for interest, taxes, insurance and repairs.

In all manufacturing enterprises of the day, one tendency is unmistakably felt. It is the direction of thorough work. To succeed in any established business one must have substantial buildings, the *best* improved machinery, the best site for obtaining necessary supplies at their cheapest. Electric lighting to-day has risen from the slough of speculation and stands side by side with other great manufacturing enterprises in importance. Not less than sixty millions of dollars are invested in lighting plants alone, and in the entire field probably not less than double that sum. Has not the time come when the same laws of strict economy which obtain in other large enterprises should govern central station construction?

Let us carefully consider our problem, plan cautiously, and expend liberally in the directions which indicate the best results. It is evident, however, that we should not expend without limit. Where shall we draw the line? I believe we are safe in expending every dollar which is sure of saving 10 per cent. interest on its investment, provided we have it to spend. The only danger in the path

1. Paper read before the American Institute of Electrical Engineers, May 18th, 1887.

Digitized by Google

seems to be the chance of such improvements as shall throw aside our present methods of producing electricity. Let us for a moment consider the possibilities in this direction. The best dynamos will to-day, in ordinary practice, convert eighty to eighty-five per cent. of the power furnished them into an equivalent of electricity. Clearly there can be but small improvement here. Coal or similar fuel is the common source of power to-day, and seems likely to remain so. The best steam plants give one horse-power hour for about one and one-half pounds of coal. The actual energy stored in that one and one-half pounds of coal would give about seven horse-power hours if it could be converted into power without loss, or, in other words, the best steam plants of to-day have an efficiency of about 13 per cent.

Prof. Houston remarked, at the last convention of the National Electric Light Association, that the field where lies the greatest chance for improvement is in the direction of thermo-electricity, the conversion of heat into electricity without the intervention of power. This is most certainly so; for if a process can be discovered which will have a reasonable efficiency, say 25 per cent., electric motors must soon supersede steam engines for power. The nature of the losses connected with the conversion of heat into other forms of energy does not, however, give much encouragement in this direction. The nature of such losses is in the diffusion of heat by conduction and radiation, which has always proved most difficult of control. If a process of simple conversion, without the attendant development of heat, can be devised, the chances of a good efficiency would be much improved, but where heat exists, there is radiation, and where radiation is, there will be serious loss. How serious, we can only judge from our experience with the steam and other heat engines. It is probable that we are safe in investments in our expensive steam plants, at least to the extent of the life of these plants. Let us then return to our subject proper. The first matter of importance to be decided in establishing an electric light station is its location. The necessary qualifications for location may be classed about as follows:

1st. A dry soil—a gravelly soil which will easily leach away the runnings from small drips or leaks, is preferable, next to solid rock. If located near a river, a wide margin of safety from flood should be allowed.

2d. If practicable, a location near a plentiful water supply should be chosen. Condensation of either high or low pressure engines is desirable in every way, and requires a large water supply.

3d. Nearness to the coal supply. If possible, locate near a navigable stream, so as to secure cheapness of handling coal and a plentiful supply of water. If not near navigable water, get a location on a railroad switch, and if possible, near the water supply. If the two conditions cannot be fulfilled, you may make your choice between them, remembering that each additional handling of coal will cost about 10 cents per ton, and extra haul about 10 cents per 1,000 feet, and, on the other hand, that condensing your engines will probably save between 15 per cent. and 25 per cent. of your coal expense. The pressing necessity for locating near the lighting field has largely passed away with the introduction of long-distance systems of incandescent lighting.

Having determined on a location, the character of building to be erected must next be considered. The most important single condition essential to the success of the electric light business is continuous and reliable service to customers. The most disastrous calamity which can befall an electric lighting business, is the destruction of its central station. The first thing necessary to prevent such a calamity, is a building practically fireproof, and I believe a brick building best fulfills these conditions. Let the walls be bare, make all floors double planked and supported on iron beams, use no wood ceiling, however seductive it may be in improving the appearance of your station; leave as few openings as possible through the floors; have a nearly flat roof with fire walls projecting above, and the building will be as nearly fireproof as it can be, and at the same time fulfill the other essential conditions of insulation, and a reasonable expenditure of capital. Before leaving the matter of fire protection, let me strongly advocate the use of some good automatic sprinkler except in the dynamo room, and especially in parts of the building unoccupied during portions of the day, a stand pipe connected with your spare pump with nozzles on each floor, a few lengths of mill hose; a cask or two set in convenient places and kept filled with water and a few firepails near are cheaply provided, and the improvement in insurance rates will soon pay for them. At Troy the reduction of rates has paid for the entire fire outfit in the saving in one year's premiums.

Before we design our station further, let me remark that the old adage that "cleanliness is next to godliness" would be a most wholesome motto for the electric light business. Dirt begets dirt, and with electrical apparatus it is by far the most fruitful source of short circuits, grounds, and consequently of burned armatures and disordered apparatus generally. Let us then so arrange our station that that most fruitful source of dirt, our boiler-house, may give us as little trouble as possible. Putting the boilers in the cellar and the engines and dynamos on the floor above is probably the worst possible arrangement next to putting all in the same room, since every opening in the floor conveys a blast of hot air, laden with coal dust and ashes. The correct method is to separate boiler and engine rooms by a fire wall and make the only opening between through a room or passage through which a strong draft of air is always passing. This we effect at Troy by means of an air shaft 6x8 feet, which also serves as a wire tower and in which wash-sinks, etc., are also constructed. The doors leading in both directions are kept shut by heavy springs, and when opened the strong draft carries all dust, smells, etc., up the chimney. This shaft is carried above the roof and the wires are carried out between the louvres of the blinds. One thing do not forget. Arrange a cellar or basement under your dynamo and engine room floor about six feet deep. You will find it infinitely convenient in connecting small pipes, etc., to the under side of the floor.

Make your dynamo room not less than ten feet high for the comfort of your men, and arrange the windows to open clear up to the ceiling, as that is where the hot air will go to escape. You may also put your windows six feet above the floor and you will save annoyance from spectators, and your men will not have so much looking to do.

The boiler house should be light in construction, having an iron roof with some outside covering, such as asphalt, to prevent sweating in cold weather. The boiler fronts should, of course, face either on an open lot or a street to facilitate handling boilers, and for the same reason the front of the boiler house should be easily removable. The floor should be of concrete not less than a foot in thickness, made of the best Portland cement, mixed about 1 part cement, 3 parts sharp sand, 3 parts stone, broken to pass 1½ inch ring.

On this may be laid a floor of flags or arch brick laid on edge. No floor of cement or of ordinary brick will stand wear.

Going back to our main building, I will follow more particularly the line of work adopted at Troy. Our lot measures 50 by 130 feet, and the problem was to develop on that space a station of a maximum capacity of 500 h. p. effective.

The lot was occupied by a mere shed covering two 80 h. p. boilers located almost exactly in the middle of the lot; one 150 h. p. compound engine just beside the boiler, belted to 48 feet of jack shaft lying parallel with the length of lot, and two feet six above the floor, the dynamos

Digitized by Google

lying each side of the shaft, the pull of the belts being nearly balanced.

The new station was laid out in a dynamo room 50 by 90, and boiler house 40 by 50 feet, arranged for a battery of four boilers 72 inches by 17 feet, stack 13 feet square at ground and 125 feet above the grates; wire tower in corner between dynamo room and boiler house, projecting into the latter. As originally laid out, the engine stood in the new dynamo room close beside the fire wall, now separating engine and boiler rooms, and the boilers further out in the dynamo room. It was decided to build the unoccupied end of the dynamo room, put in engine power connected with the old boiler, shift the station, abandon the old engine temporarily, build the rest of the new station over the old, put in new boilers, then connect them and disconnect the old boilers, remove the old boilers, and finish the inside of the building. The company changed hands on May 23, 1885, and on September 1st the old station was shut down at midnight, and the dynamos shifted to the finished part of the new building, and at six the following evening the station was in full operation in its new quarters. The plant then comprised about 600 Weston incandescent lights and some 20 arc lights. The remainder of the work was merely a question of time, and the station was first operated on its new boilers on December 17, 1885. At the same time about 15 miles of pole lines were constructed, and some thirty miles of wire strung for the city contract of 130 lights.

The general construction of the Troy station is believed to cover the average conditions met with in central station construction, and is therefore particularized. In the arrangement of dynamos and engines we desired to attain the best economical results in the following items:

1st. Best average economy in coal.

2d. Best average economy in transmission of power to its work.

3d. Best economy of attendance.

4th. Best economy of oil, waste, etc. Our customers required a day service, and we had to take this into account in our selection of engines for power, and in their arrangement.

These conditions were to be borne in mind in the selection of our engines, and, in addition, the most important condition of reliability. Compound engines offered us the best coal economy, with maximum load, but had the disadvantage of poor economy with light loads. Corliss engines would occupy too much room, and both required shafting and counters to speed up, and would have forced us to use the second floor for dynamos, with the attending disadvantages of extra help and upright belting. We finally decided on using the best type of high speed engines, and purchased three engines of 9x14 cylinder, each belted to a jack-shaft 16 feet long, and each driving four 110-light incandescent dynamos, belted in pairs from opposite side of the shaft. The lengths were arranged to be coupled by friction clutches. This arrangement gave us a very uniform rate of coal economy, though not a very high one. The arrangement of belting made the shaft friction very small. The old compound was set to work on its proper duty of driving a fixed load of city lights.

The relative merits of compound, Corliss, or high speed engines are well understood, and the circumstances must in every case decide the type of engine proper to be used.

Where the maximum of output is required from a small space, high speed becomes a necessity. Where the load is very variable a number of smaller engines will give as good average coal economy as a single larger engine, with less chance of a complete failure. Where the load is heavy and constant, a pair of large engines will give the best economical results and at the same time cover the possibility of a complete breakdown. The new triple expansion engines, which are rapidly replacing all others in ocean and lake steamers on account of their wonderful coal economy, will probably displace all others in the field.

Condensing high speed engines have not met with much favor, but we find at Troy that our "Straight-Line" engines work quite as quietly under 28 inches vacuum as without, and that the coal economy is considerably improved; probably from 15 to 20 per cent. on the engines condensed. They have also the advantage of giving us much more power for cases of emergency.

As to boilers, I am strongly in favor of boilers of large size; ours measure 60″x17 feet, and are of Nashua "Indian head" steel, $\frac{7}{16}$ shell, $\frac{1}{2}$-inch head, and have 136 3-inch tubes. The dimensions of the tubes 3″x17 feet would be out of all proportions for ordinary drafts, but our stack 125 feet above the grates gives us ample draft and the small tubes a great evaporating surface, and consequently a better evaporation. I am afraid I shall be considered a little unsound of mind when I state that with these boilers we are able, and do, evaporate with a mixture of one part bituminous to two of yard pea and dust, nine pounds of water per pound of coal, and with ordinary buck-wheat coal ten pounds of coal, feed water at 200 degrees. But such is the case, as I shall be happy to show any one visiting us. This is not pounds of combustible, but of coal. I have always found the ashes to cost just as much per ton as the fuel part of the coal, and therefore consider that they have no place in the relation of evaporation per dollar. We keep a daily and nightly record of our evaporation by a Worthington meter, which is on the boiler feed, and let me say that the bad reputation for veracity of meters in general will not apply to our meter, as repeated tests show a nearly constant error of 2 per cent. low. I may further say that our meter, though a Worthington, has no connection with the *Electrical Review*. I merely state this to protect the meter from undue suspicion. (Laughter.)

For boiler feeds provide a reliable injector in addition to feed pump, which latter should always be used in connection with a good heater. An extra feed pump may be connected as a fire pump, and should be used regularly for some such service as washing out boilers, to ensure its being in good order.

Attention to surface and bottom flues is, of course, a daily duty.

As to fittings use some one kind of valve; get a good kind and stick to it. Price should have no place in the first choice of valves. Get a good one with removable seats and discs and you will save a world of trouble and a deal —not an electric light deal—of money in a few years time. Let me remark that everything we have in bottom blow-offs has failed, except plain plug valves. The failure seems to come from scale, which will stick under the gates and seats, and bend them out of shape when closed. An extra large valve in the blow-off discharge is desirable in case of a failure of a blow-off valve.

In piping of all kinds discard elbows and use only T's, you will frequently save taking down an entire line of pipe to make some connection by so doing, and the T's are most convenient for examining and cleaning the pipes. You should also obtain all your fittings and pipe of one party to ensure good fits. Threading tools are seldom alike and a small variation will give endless trouble with leaks.

Cover all steam pipes, and remember in choosing a covering that it is not the material which you cover with, which makes the non-conductors, but the confined air spaces in the same. Get air spaces and get them so arranged that the air cannot circulate between hot and cold surfaces. Remember also that you can tell nothing by the feeling of the outside of a covering about its effectiveness. Sensations of heat and cold are intensified by the conducting capacity of the object touched. A piece of metal attached to a steam covering till hot will convince you of this. It can be no warmer than the covering, but it feels so.

In touching on the electrical apparatus I feel that I am treading on delicate ground, and I shall try and step

Digitized by Google

accordingly. The principal elements of ordinary wear in dynamos are

1, Burned coils in the armature; 2, wear of brushes; 3, wear of commutator; 4, wear of boxes or journals.

In regard to burned armatures I will say that judgment should be exercised in the choice of a system as to the liability of such an accident, and this being determined choose a machine whose armature is most readily repaired. Gramme and similar ring armatures are probably the most easily repaired. Siemen armatures and all armatures with lapped coils must go to the factory for a good job.

As to brushes, the cheapest by far both in first cost and wear, are the single leaf, split brush. Multiple brushes are usually used in commutators with many segments, and there seems to be some relation between the number of segments and wear of brushes.

Commutators of many segments are less desirable than those of few. The segments can usually only be changed by putting on a new commutator and they seldom wear true. The segments on commutators of fewer bars are usually arranged to be easily removed and can then be turned up and replaced.

Plain babbitted boxes or bronze bushings are about on a par for convenience in renewal. Bronze has the advantage of not being liable to melt out and cause a shut down, and a little patience will almost always succeed in cooling them down. For belting probably nothing is better than double pasted leather belts if well made. For large belts a few rivets must be put in.

Arc lamps should be devoid of glycerine, and not easily shaken out of adjustment. The lighter and smaller lamps are, the better for handling. Arrange all inside wiring of some first-class high insulation wire, especially on high tension circuits.

In the Keystone station in Philadelphia I first saw oil conducted to each machine oiler and cylinder cup in pipes. I heartily approve this system as a saving both of oil and waste.

In conclusion, I will suggest two rules to govern central station construction.

1. Expend every dollar which will return 10 per cent. on its investment in addition to maintaining itself, including, of course, interest, taxes and wear and tear.

2. After carefully investigating, estimating and planning out the capacity of your station, make a large guess as to what you require, and multiply by two.

DYNAMIC ELECTRICITY.

BY CARL HERING.

CHAPTER VIII.—FIELD MAGNET COILS.

ALTHOUGH methods have been suggested for calculating directly the size of the wire and the number of turns in field magnet coils, from the magnetism required, yet until such methods have stood the severe test of repeated application in practice, they must be regarded merely as suggestions which may or may not be more trustworthy than the methods already in use. It can hardly be expected that any new methods based on calculations only, will ever prove to be more reliable and sure than the well tested method to be described and which is based on the actual performance of the machine.

There are a number of factors which enter into such calculations, which are either unknown or uncertain, and which will, therefore, make the results less reliable. Until these quantities are known any determination of the coils based merely on calculations without testing the machine, will be approximate only. Among these uncertain or unknown quantities are the magnetic qualities of the particular iron used, the effect of the shape of the magnetic parts, the air space in the magnetic circuit, the magnetic leakage, the resistance equivalent of the self-induction of the armature and field magnet coils, the effect of the number of pulsations or of armature coils, the Foucault currents in the armature coils and in the pole pieces, the counter magnetism in the armature commonly called the magnetic lag. It is known, however, that under certain conditions, easily obtainable in practice, the effect of a number of these quantities or proportions is so small that it may be neglected. The effects of some may be eliminated by taking as a basis of the calculations the known results of a similar machine of the same general type and proportions, though not necessarily of the same actual size. Recent investigations[1] in apparently the right direction, may however lead to the determination of certain reliable constants and relations which will materially aid the engineer in calculating more definitely the relations between the exciting coils and the field, without first constructing a number of trial machines.

As described before, it is the electromotive-force which the machine generates and maintains, the current being dependent only on this and on the total resistance in circuit. This electromotive-force depends on the armature, on its speed and on the magnetism, which latter depends on the iron parts and on the ampere-turns. Therefore, if the armature and frame have been constructed as described, and the safe speed determined upon, the only other factor which remains undetermined and which may be made to correct any small errors or inaccuracies in the determination of the armature and frame, is the winding of the coils.

This may be determined with all due accuracy by the following method: When the machine is completed in all its parts except its coils, erect it and place on the magnet cores temporary coils of a known number of turns. These coils should all have the same number of turns; the size of the wire will depend on the electromotive-force and current of the separate exciting machine or battery which must be used to supply them with current; it should be large if the exciter gives a strong current of low electromotive-force, and small if it gives a small current of high electromotive-force. They may be wound on shells of brass or ordinary tinned iron, and should have a depth of winding about equal to that which the final coils should have, in order that the inaccuracies due to different thicknesses of coils may be eliminated.

The machine is then run at its proper speed as a separately excited machine, the current for the coils being supplied by a separate dynamo or by a storage battery, which must be so arranged with adjustable resistances or other regulating devices, that the current in the coils may be varied at will. The current from the machine is discharged into a large rheostat, or in the absence of such a resistance it may be sent into a battery of storage cells or into a circuit of incandescent or arc lamps, though the latter is not to be recommended, as the arc lamps make the current too unsteady. The exciting current is then varied and adjusted until the machine gives its proper potential when the current has the required strength, the brushes having first been set to the proper position to avoid sparking. When all the adjustments have been made and the current and potential measured to see that they have their desired values, the current which flows through the exciting coils should be measured as accurately as possible. This exciting current is then multiplied by the total number of turns in the temporary field coils, which gives the number of ampere-turns that are required to excite the magnets of the machine while it is generating its proper potential and delivering the proper current. From this number of ampere-turns the proper size of the wire and number of turns for the new coils of the machine can readily be determined, as will be described. The magnetism of a core depending only on the ampere-turns, it is immaterial whether these are generated by many windings with a small current as in shunt machines, or by few windings with a strong current

1. Proceedings of the Society of Telegraph Engineers, November 11, 1886. Kapp on characteristics of dynamos.

Digitized by Google

as in series machines, or by a combination of both as in compound machines; all that is necessary is that the total products of the current and number of turns of wire be the same.

The following precautions should be taken in making this preliminary test for determining the ampere-turns:—The temporary coils of the machine when separately excited should be connected in series with one another, for if they are in multiple arc an error may arise from a possible unequal distribution of the exciting current in the different coils due to different resistances. In the absence of an exciting machine or battery the temporary coils may be supplied with current from the machine which is being tested; they may then be wound with tolerably fine wire and have an adjustable resistance in series with them, the connections being made like those for a shunt machine, the shunted current being added to the main current as part of it. Or the temporary coils may be wound with coarse wire and connected as in a series machine, the adjustable resistance being in that case connected as a shunt to the coils, and the potential of the machine being measured at the brushes and not at the poles, as some of the potential is used in the coils.

If the finished machine is to be a series wound machine a portion of the potential of the armature is consumed in sending the current through the magnets. This may be as low as 1.5 or 2% of the whole potential in large well built machines, and as high as from 15 to 20% in smaller cheaper machines; it represents the percentage of energy required in the magnets. In the preliminary test for determining the ampere-turns this should be taken into account, the exciting current being increased until the potential of the machine is that which will be required for the magnets in addition to that required for the external circuit. If the finished machine is to be shunt wound, a fractional part of the whole current generated will be required for the magnets; this varies from 1.5 to 2% of the whole current in large well built machines, and is as high as 15 to 20% in small or cheap machines. In the test for the ampere-turns the machine should therefore be excited until the current is equal to the sums of the main current and this shunted current. In compound machines both of these corrections should be made, the whole percentage of energy being divided between the two sets of coils according to their functions. For instance if 3% be allowed for the magnets, $\frac{1}{3}$ of this or 1% of the potential might be allowed for the series coils, and $\frac{2}{3}$ or 2% of the current for the shunt coils.

The magnets should not be over-saturated except when it is desired to "steady" the current by having the magnets less sensitive to changes of current in their coils. This applies, of course, only to self excited machines; in those in which the magnets are separately excited, as in some central station plants, or as in most alternating current machines, there is apparently no reason for over-saturation. Well built compound machines should never be over-saturated, nor even too near the point at which saturation appears to be complete, as it is then difficult, if at all possible, to wind them compound for a constant potential. How to determine, before winding the magnets, whether they are over-saturated by the required magnetism, will be set forth in a subsequent chapter on examining machines.

SEPARATELY EXCITED MACHINES.

If the finished machine is intended to have its magnets energized by the current from a separate machine the calculation of its winding becomes very simple. Suppose the preliminary test with temporary coils, just described, showed that 20 amperes were required, and that there were 250 turns or windings on each coil, the type of magnet frame being that shown in figure 26, chapter VII., in which there are four coils; there will then be $4 \times 250 = 1{,}000$ turns, which with 20 amperes gives a total of 20,000 ampere-turns as a measure of the magnetism required. The number of ampere-turns or ampere windings thus determined will hereafter be represented by $(a\,W)$.

To determine the winding for the finished machine assume any suitable current and divide this number of ampere-turns by it; this will give the required number of windings or turns of wire, which again divided by the number of coils gives the windings per coil. Any suitably sized wire may then be chosen, which when wound to the required number of turns will not make the coil too large, a good practical guide for which is to make the depth of the coil about $\frac{1}{8}$ the diameter of the core when round, or $\frac{1}{8}$ of the lesser diameter when oval. A more direct method of finding the proper size of the wire is to divide the area of cross-section of the coil space in square inches (that is the length of the coil multiplied by the depth or thickness) by the number of turns of that coil; this will give approximately the space for each wire, the square root of which is the diameter of the insulated wire in inches.

The current for such magnets should be chosen with reference to the cost of the wire for the coils, the cost of winding it, and the length of the leads from the exciting machine. Considering the cost of the wire only, the current should evidently be as strong as possible and the potential correspondingly low, in order to increase the size of the wire as much as possible, as coarse wire is cheaper per pound than fine wire, and it may be assumed that the weight of coils having the same cross-section of coil space is nearly the same whether coarse or fine wire is used. Considering the cost of winding, however, a limit is soon reached. Although it costs less to wind fewer turns of coarser wire than many turns of fine wire, the cost again increases when the wire becomes so thick as to be unmanageable. Considering both of these factors the wire should be chosen as large as it is easy and cheap to wind. If the exciter is at a great distance from the machine the additional cost of the leads, for a strong current, may necessitate taking a smaller current, and, therefore, more turns of finer wire on the magnets; but this case would probably occur seldom, if ever, as the exciting machine is generally near the other.

In some cases it may be preferable to reverse this method and to determine first the largest wire which it is practicable to use, then find how many turns can be wound into the given coil space, and finally by dividing this number of windings into the number of ampere-turns per coil, find what the current must be.

The case may occur when the magnets must be wound to suit a certain exciter giving a definite current and electromotive force. The current for the magnets being fixed, the number of windings are determined by dividing it into the ampere-turns $(a\,W)$. The size of the wire must then be chosen so that when wound to the required number of turns its resistance is such that the potential required is within the limits of the capacity of the exciter. In other words, if C and E are the available current and potential of the exciter, the resistance of the coils must not be greater than $R = \frac{E}{C}$. On account of the self-induction of the coils, the heating, a possible slight error in the diameter of the wire, or other factors increasing the apparent resistance, it should not be as large as $\frac{E}{C}$, but should contain a "factor of safety" by making it, say 15 to 20% less.

The size of the wire could be determined by trial by calculating the resistance of the required number of turns with different sized wires, but the following method will be found to be more direct.

Let d, represent the diameter of the bare wire in mils or thousandths of an inch;
l_m, the average length of one turn in inches;
R, the resistance of all the magnet coils in legal ohms;
W, the total number of turns on the magnet coils of the finished machine;
a, the current in amperes in the magnet coils of the finished machine;

Digitized by Google

($a W$), the ampere-turns obtained from the preliminary test;

θ, the specific resistance (metric) at the allowable temperature of the coils.

The resistance of the finished coils will then be

$$R = 50.13 \frac{W l_m \theta}{d^2}$$

and according to Ohm's law,

$$R = \frac{v}{a}$$

in which v is the potential in volts which is consumed in the coils. Hence it follows that

$$d = \sqrt{\frac{50.13 (a W) l_m \theta}{v}}$$

or assuming θ equal to .0162 and the temperature about 70° F,

$$d = \sqrt{\frac{.875 (a W) l_m}{v}}$$

in which it is only necessary to substitute the particular values, and reduce it, to find the diameter directly. v should in this case be 15 to 20% less than that which the exciter will give, in order to include the factor of safety above refered to.

The writer well recognizes, that it is unfair to use such a table in estimating the comparative value of dynamos. The figures are interesting as they show the excellent results in activity of copper attained by several of the best known makers under the most diverse conditions. A few of the examples illustrate the difficulty of discovering a thoroughly impracticable design for a dynamo.

To complete the comparison there might be added the special use for which each machine was designed. This can be inferred in most cases from the E. M. F. and current. The use to which a dynamo is to be put must have much influence on the amount of wire on the armature, this being especially noticeable in arc light dynamos where it is best to sacrifice activity of wire and efficiency to gain greater stability in the lights.

The columns in the table have the same signification as in the previous table: i., ii. and iii., contain respectively volts per foot of wire, volts per foot of wire and per foot per recorded periphery velocity, and volts per foot of wire and per revolution. The headings of the other columns are self-explanatory.

I have availed myself of the note of Mr. H. Ravenshaw, in the *Electrical Review*, London, of April 29th, in respect to the figures of the Goolden-Trotter machines. Figures for several other machines have been added to the original table.

PHYSICAL LABORATORY, CORNELL UNIVERSITY, Ithaca, N. Y., May 17th, 1887.

ON THE DIFFERING TEMPERATURE CO-EFFICIENTS OF THE DIFFERENT COILS OF A FINE RHEOSTAT.[1]

BY PROF. W. A. ANTHONY.

THE title of this paper should rather have been "A Description of Experiments by which the Differing Temperature Co-efficients of the Coils of a Fine Rheostat were Discovered." I thought the experiments of sufficient interest to warrant a description, and I find, on writing the paper, that the experiments occupy the greater part of it.

In 1884 the Cornell University ordered of Latimer Clark, Muirhead & Co., of London, a fine rheostat and bridge of special construction. Among other things it was specified that the resistances of the coils of both bridge and rheostat

1. Read before the American Institute of Electrical Engineers, May 18, 1887.

Digitized by Google

should check among themselves to 1-100th of one per cent., and that everything should be done to make the instrument as accurate and reliable as it was possible for such an instrument to be. On its arrival it was found not to fulfill the requirements as regards accuracy, the coils differing among themselves in many cases by more than 1-10th of one per cent. It was returned to the makers for readjustment and did not come back to the university for several months. On its return it was found that the adjustments had been much improved, but still did not come within 1-100th of one per cent. It was, however, finally accepted at a reduced price, the writer proposing himself to perfect the adjustment. Press of other work prevented this being done, and, last November, when a problem requiring the highest attainable accuracy in the comparison of two resistances presented itself for solution, this rheostat was used for making the comparison, it being proposed to afterward determine and apply the corrections for the errors of the individual coils.

The problem was, to find by experiment the ratio of the constants of the suspended and stationary coils of the large galvanometer, a description of which has already been read before the Institute. The constants of these coils were determined by measurement while they were being wound and the experimental determination of the ratio was undertaken as a check on the measurements. To determine this ratio, a current is made to divide between the stationary coils on the one hand, and the suspended coil on the other, but in the reverse direction, so that the two currents shall have a differential effect on the needle. The resistances are then adjusted till the needle is unaffected when the current in both branches is reversed. The constants of the coils in the two branches are then directly proportional to the currents flowing, and, therefore, inversely proportional to the resistances of the two circuits.

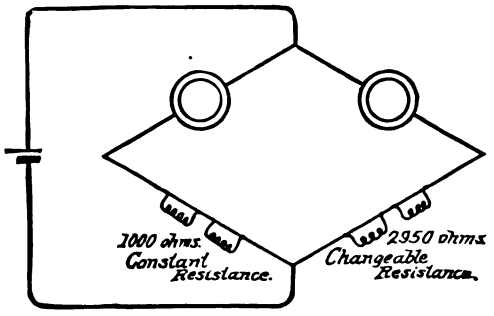

FIGURE 1.

To obtain the ratio of these resistances, they were arranged as two branches of a Wheastone's bridge, as shown in figure 1, the other two branches being made up from the rheostat referred to above. The apparatus was arranged and the tests made by Mr. Ryan, a senior in electrical engineering, and Mr. Hammon, a graduate student of electrical science.

The first trials showed that nothing could be done with binding screw connections and sliding contacts. All permanent connections were therefore soldered, and all others made with mercury. After this was done, irregularities still existed which were traced to varying temperatures, resulting from the fact that the building in which the galvanometer is mounted is of wood and warmed by a wood fire in an "air-tight" stove. The fire was allowed to go out, and the work continued at the temperature existing outside, about zero centigrade. Times for the experiments were chosen when the temperature was quite uniform, and the results were found to agree very well among themselves, but, to our surprise, they were totally different from the results obtained at the higher temperatures. The following table will show how the results ran:

Room warmed.		No fire in room.	
Temp.	Ratio,	Temp.	Ratio.
21.4	2.9520	Dec. 7 1.7	2.9492
21.3	2.9523	1.7	2.9492
20.8	2.9529	1.8	2.9492
20.3	2.9524	1.6	2.9492
20.2	2,9526	Dec. 8 3.7	2.9495
20.2	2.9528	3.8	2.9498
19.1	2.9529	3.8	2.9497
		3.8	2.9497
		etc.	etc.

Here is a difference of one-tenth per cent. for a change of temperature of about 20° centigrade. It should have been stated that the ratios above are the ratios of the two resistances as read from the rheostat; that one of the resistances was always 1,000, and of the other, which was nearly 3,000, only the units and tenths coils were changed.

A study of the construction of the galvanometer, and a discussion of the effects of temperature upon it, made it clear that the change indicated above could not be a real change in the ratio of the constants of the coils. It must, therefore, be looked for in the rheostat. To test this conclusion, different sets of rheostat coils were used in making up the arms of the balance, and tried at high and low temperatures. In one case the ratio was apparently larger at the lower temperature, the reverse of the result shown in the tables above. But the crucial test was suggested and tried by Mr. Ryan. He took the rheostat out of doors and then subjected the galvanometer and all accessory apparatus, except the rheostat, to changes of temperature. The rheostat then indicated the same apparent ratio for all temperatures of the galvanometer.

It is certain, therefore, that a change of temperature of 20° causes a change in the relative resistances of two sets of coils in this rheostat to the extent of 1-10th of one per cent., that is, the temperature co-efficients of the different coils are not the same, and it is, therefore, no wonder that the makers could not adjust the resistances more accurately. Such differences of temperature co-efficients might well occur if the wire of which the coils are wound was taken haphazard from different lots, made, perhaps, from different lots of metal. If makers of fine instruments are not careful to select wire that is sure to be of one composition for the construction of resistance coils, it is no wonder that it is so difficult to attain to a high standard of accuracy in electrical measurements.

But there is another possible explanation for the differences found in this instrument. The low resistances are of coarse wire, and this, from different temper or from different treatment in drawing, might not have the same co-efficient, although made from the same metal, as the fine wire. In short, I believe that, for the construction of an accurate rheostat, the coils should not only be from the same lot of metal, but should all be drawn to the same size and subjected to the same treatment while being drawn. The wire chosen should be fine enough for the coils of highest resistance, and coils of low resistance should be made by winding two or more of the same wires in multiple arc.

THE RELATION BETWEEN THE CROSS-SECTION OF THE IRON IN ARMATURE AND FIELD OF THE GRAMME DYNAMO.[1]

BY DUGALD C. JACKSON.

THE relation between the cross-section of iron in the armature core to that in the magnet limbs in a dynamo machine is an important one. On its proper adjustment, in an otherwise well-designed machine, depends the attainment of maximum efficient output per pound of wire with minimum of iron. Of two machines designed for a given purpose, the one with a Siemens armature and the other with a Gramme ring, the path of the lines of force through

1. Read before the American Institute of Electrical Engineers, May 18, 1887.

Digitized by Google

the armature of the latter machine will usually be considerably longer than in that of the other. It is evident that special care should be exercised to make the Gramme armature of sufficient area of cross-section that its magnetic resistance be not increased unduly. Siemens armatures from mechanical principles call for a goodly amount of iron, while an increase of cross-section in a Gramme armature increases mechanical difficulties considerably. Consequently, Gramme armatures usually have considerably smaller cross-section than Siemens armatures in machines intended for a similar use, magnetic conductivity being sacrificed for mechanical convenience in the Gramme. How far this sacrifice may be carried without impairing the value of the machine must of necessity be specially determined for each individual case.

The question of how far the characteristic, and so the output of a machine is influenced by variations in the cross-section of the armature could be determined by the Hopkinsons' very beautiful method of predetermining characteristics. In a machine, the outline and dimensions of which are determined by conditions imposed, the curves of magnetization, such as Dr. Hopkinson used, would be fixed for the field and air space. By plotting curves for armatures of various cross-section, the area giving the best characteristic, and yet not unduly decreasing the internal diameter of the ring, would be evident. The value of the leakage ratio, v, might be estimated by Prof. George Forbes's method, if the shape of the diagrams were not too complicated.

An experimental solution of the problem for a little dynamo was made this term in the physical laboratory at Cornell University. If we had armatures for one dynamo made with cores of various cross sections, the best section would be apparent from the characteristics. However, it is not necessary to wind the armatures, but simply to measure the number of lines of force passing through the armature for various magnetizing forces—that is, observing the data for a curve of magnetization. This may be done in several ways.

In the experiment referred to, a single turn of wire was placed around the section of the armature core perpendicular to the direction of the lines of force. This was connected with a ballistic galvanometer. The swing of the needle of the galvanometer was observed when the current was reversed in the magnetizing coils on the field. The swing was thus proportional to 2 H A, A being the area of the turn of wire, and H the induction per unit area. Knowing the magnetizing current and the corresponding swing for a number of points for each of several different armatures, the corresponding curve of magnetization may be plotted. These curves are exactly similar to the total characteristic of a series dynamo or the internal characteristic of a shunt machine.

The field of the little dynamo experimented upon is of the single horseshoe type standing upon the yoke. This is rectangular in cross-section. The limbs are cylindrical and are held in place on the yoke with two pins each, the contact surfaces being perfectly plane. The yoke and limbs are of the best Norway iron. The pole pieces are of a very good quality of cast-iron and are chambered to fit the upper ends of the limbs, which enter for a length of 7 cm., making the area of contact considerably greater than the cross-section of the limbs. The cross-section of the pole pieces is much greater than that of the limbs. The bore of the pole pieces is 10.8 cm. in diameter, there being a gap at the top and bottom subtending an angle at the centre of the bore of 51°. The width of the surfaces on either side of the gap is .3 cm. The corners of the pole pieces are all rounded off.

Following are the dimensions:

Limbs (cylindrical)	
Length	20.3 cm.
Diameter	6.35 "
Area of cross-section	31.66 sq. cm.
Distance apart from centre to centre	17.9 cm.
Yoke (rectangular).	
Length	26.8 cm.
Width	8.2 "
Depth	6.9 "
Area of cross-section	56.6 sq. cm.
Pole pieces	
Height	10.2 cm.
Width	10.2 "
Bore	10.8 "
Mean area of cross-section	—sq. cm.

The magnetizing coils consist of 785 turns on each limb, making a total of 1,570 turns.

The armatures were composed of thin punched discs of soft wrought-iron, obtained through the courtesy of Thos. Pray, Jr., of Hartford, Conn. The discs were insulated by dipping them into shellac varnish, and then built into armatures by placing them on wooden mandrels turned to fit their internal diameter. The variation in the cross-section of the armatures was obtained chiefly by using armatures of the same number of discs, but of different internal diameters. As it was not possible to secure discs with the proper internal diameters to give all the area desired, some of the armatures were composed of fewer discs. In these, thin spaces were left between the discs and the area inclosed by the exploring coil was slightly greater than that of the iron. The effect of this has been neglected as too small to be appreciable. The areas were obtained by multiplying the thickness of the discs, which was .0462 c.m., by the number on the armature.

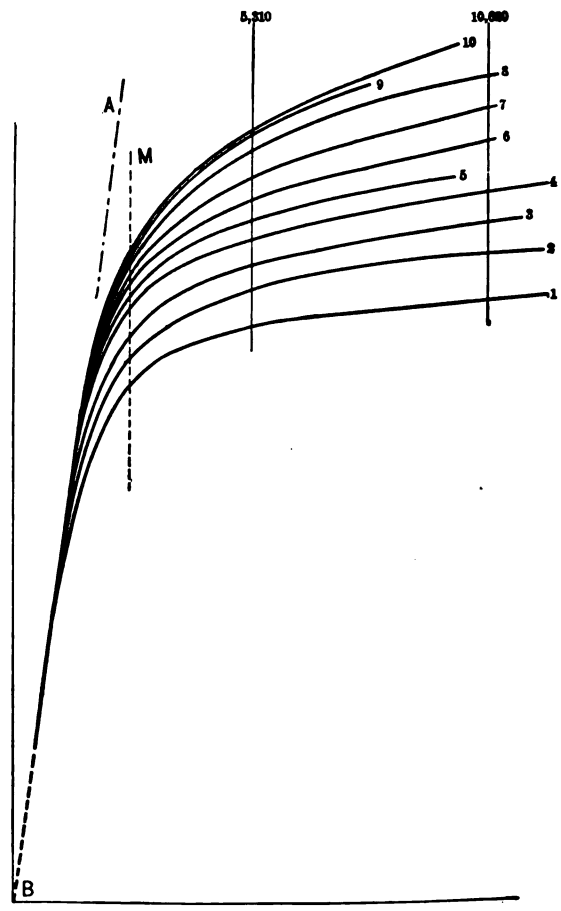

FIGURE 1.

The magnetizing current was furnished by a number of storage cells. In the circuit of these were placed a tangent galvanometer and the magnetizing coils. A reversing key was so placed in the circuit as to simultaneously reverse the current in the galvanometer and coils. The magnetic induction was measured by a ballistic galvanometer, as already explained. The observations were

Digitized by Google

taken by Mr. F. R. Jones, an engineering student working in the laboratory. The regularity of the curves attest the care with which he carried out the work. I have here a rough sketch of the curves determined by Mr. Jones, which, I think you will agree with me, are very interesting.

The following, in figure 1, are the areas of the cross-section of the armatures and their ratios to the cross-section of the magnet limbs:

Armature	No.	1	17.75	cm		Ratio	0.561
"	"	2	19.23	"		"	0.607
"	"	3	20.70	"		"	0.654
"	"	4	22.19	"		"	0.701
"	"	5	23.66	"		"	0.747
"	"	6	25.14	"		"	0.794
"	"	7	27.36	"		"	0.864
"	"	8	29.18	"		"	0.922
"	"	9	34.49	"		"	1.09
"	"	10	42.44	"		"	1.34

In curve No. 1, where the armature has little more than half the area of the limb, the turn in the characteristic is sharp and the straight line representing the upper portion of the curve is almost horizontal. The rapid great increase of magnetic resistance shown by the curve to the right of the line M must be due entirely to the saturation of the armature. As the area of the armature increases the turn in the corresponding characteristics grows into a longer sweep and the upper part of the curve takes an increasing angle with the horizontal. Curves Nos. 9 and 10 are given by armatures greater in cross-section than the limb, and though there is a difference in their areas equal to a quarter of the area of the limbs, there is very little difference in the total induction passing through the armature. The curve No. 10 then very probably nearly represents the curve of magnetization of the iron in the field and the air space. The straight line which constitutes the lower part of the characteristic, being the backbone of the curve, as it were, must very nearly represent the line of magnetic resistance of the air space. By air space I mean the space between the pole-piece and armature.

Looking at the curves, you see the armature No. 1 was highly saturated, or, in other words, had become of enormous magnetic resistance before the permeability of the field began to decrease appreciably. On the other hand, armature No. 9 has increased in magnetic resistance very little up to the point to which the characteristic has been carried, while the field is quite saturated. Between these extremes there are varying degrees of relative saturation of the armature. In curve No. 7, the field and

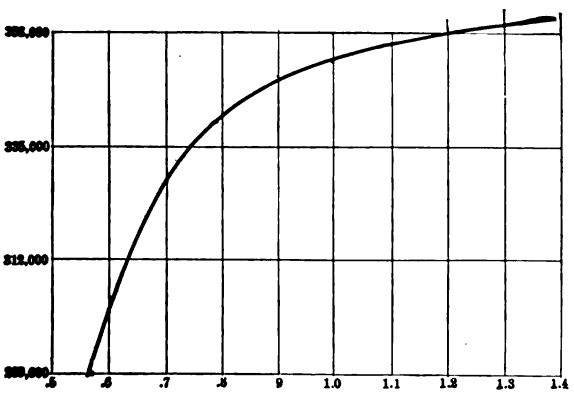

FIGURE 2.

armature are apparently at about equal degrees of saturation throughout. The curve shown in figure 2 illustrates the effect on the total induction through the armature of the ratio of the area of the armature to that of the limbs. As ordinates are plotted total induction through the armatures taken from the characteristics on the section line M. The abscissas are ratios of the cross-section of the armature to that of the limbs.

This curve is exaggerated in vertical scale so that its character may be more plainly seen. It shows obviously that the induction through the armature increased quite rapidly when the armature core was increased in area from .5 of that of the magnet limbs to about .75 that of the limbs. From .75 to .9 there is still an increase of induction with increase of armature core, though not so good as before, and beyond .9 the increase is of no practical importance.

If the section M, figure 1, had been taken farther up the curves, the relative increase of total induction with increase in the area of the larger armature would not have been so marked.

The section M is taken at 2,660 ampere-turns; that is, an absolute magnetizing force of 33,420. The absolute total induction for this magneto-motive force are shown in the curve, figure 2. These were determined by comparing the throw of the ballistic galvanometer given by the armature with that given by a standard coil turned through 180 degrees in the horizontal component of the earth's field. The value of the horizontal component at the place of the standard coil was determined by comparison with that in our magnetic observatory by the use of the compensated magnetometer.

We may safely assume that the cross-section of the armature should be about .75 of the cross-section of the limbs if the wire on the armature is to have the greatest activity without an excessive quantity of iron in the core. By making the cross-section of the armature .6 of that of the limbs, a loss of 10 per cent. of the total induction when the ratio is .75, would be made, and consequently an equal loss in E. M. F. and the output of the machine. This is a case where the permeability of the field magnet is equal, or very nearly equal, to that of the armature. If the permeability of the armature core were greater than that of the field, the area of armature could be a smaller ratio.

No allowance has been made in this for the effect of a current in the armature. That should at any rate be small, except in the case of arc-lighting machines, where a great number of turns of wire are placed on the armature with the purpose of gaining stability in the lights.

The absolute intensity of the magnetic flow per square cm. in the armature was quite high. In armature No. 5, the section of which is practically .75 that of the limbs, an induction of 14,000 per square cm. was given by 2,666 ampere-turns. For about 10,000 ampere-turns the induction was 17,000 per square cm; 10,000 ampere-turns gave an induction of 11,000 per square cm. through armature No. 10 and about 18,000 in armature No. 1. The latter was increased to nearly 19,000 by 12,500 ampere-turns.

The induction per square cm. corresponding to the best conditions in this machine is 14,000 per square cm. This is high for a dynamo. I believe Dr. Hopkinson has placed the figure in the Edison-Hopkinson machine as 8,000, and if true, this is probably seldom exceeded. I am aware that the value apparently reached 20,000 in the Manchester dynamo in Hopkinson's late tests, but that high value can not be given much weight, even though the armature was pretty well saturated. I may be placing the limit entirely too low, as I have a number of records where from 10,000 to 15,000 is claimed, but simple claims are endowed with great uncertainty.

It may be interesting to note the ratio of the areas in two or three dynamos of ordinary size. It is impossible to estimate the area of iron in an armature with wire on it, because of the uncertainty in the space occupied by insulating material between the iron discs. In the record of their late tests the Hopkinsons have given the areas of the armature and magnet limbs in the Edison-Hopkinson and the Manchester dynamos. In the Edison-Hopkinson machine the field had probably nearly the same permeability

Digitized by Google

as that of the armature core. The cross-section of the armature was about .8 that of the field, and the field was considerably more saturated than the armature. In the Manchester dynamo, the field probably had a lower permeability than the armature, and they were about equally saturated. The cross-section of the Gramme ring in this machine was about .6, that of the cross-section of the field.

STORAGE BATTERIES IN PRACTICE.[1]

BY EDWARD P. ROBERTS.

SINCE I had the honor of reading a paper on storage batteries at the annual meeting of 1885, we have discarded storage batteries distributed in various localities as the source of supply of current to our incandescent lamps, and have now all lamps connected with our incandescent dynamos. Having, however, a large number of cells we have placed in position at our station, about 1,200 of the same, charging them at night and using the stored current for day lighting and power, both of which are small in amount. In case of an accident to our machinery at night we could use our storage plant to tide over the time required for repairs, or until the majority of lights could be turned off. We have not yet had call, however, for such service, although we always have the batteries charged to a considerable extent before dark.

Since 1885 we have tried crockery and glass cells, with plates *suspended* in the same from glass rods and separated by glass rods from each other. This was a great improvement. The cells are placed on beams of a triangular cross-section, having a four inch base, which, in turn, rest on glass insulators, Western Union pattern, screwed on pins fastened on cross pieces. The beams are first painted and then given a coat of paraffine. The insulation from cell to cell is much improved thereby. When lead cells are used they are placed on porcelain insulators on the beams; flat places being cut on the vertical angle of the beam.

I am informed, with what degree of correctness I do not know, that storage batteries have been much improved, lately, over those with which I have had experience, but, even if such should be the case, I should hesitate to use them where gas lighting is cheap and where it might be desired to use only a *few lights* in *each* of a *large* number of localities separated by considerable distances. For special cases, however, I have no doubt the storage batteries can be used advantageously, particularly when the advantages of incandescent electric lighting are considered as being of financial value.

A few of the disadvantages arising from the conditions in the first part of the above paragraph, are :—

1st. A large plant in each locality is needed because of possible drain on same. The ordinary use in a residence may be 15 lamp hours and the possible use 100 lamp hours. This is an extreme example, but is not exaggerated as it was the necessary margin we had to provide, when we had storage plants in each house requiring light, for from 15 to 20 per cent. of our customers.

If several customers can be supplied from one battery plant the margin of extra supply can be reduced. In such case it will be necessary *either* to connect all the customers on all the batteries connected in multiple arc, and then disconnect the batteries and charge same in series, or, if it is desired to use a meter system in which discharge bears a certain proportion to charge, an attendant must be ready to throw extra batteries on circuit needing same, and note name of customer using extra supply.

2d. A large number of plants means a number of small stations to maintain and at which to keep supplies—distilled water, acid, etc.

3d. With a number of small stations it is difficult to regulate E. M. F. to current desired. However small the percentage of E. M. F. lost in the discharging wires the E. M. F. of the batteries should rise as lamps are turned on, or the lamps will be below candle-power, when a number are used, if for one or two the proper E. M. F. is used; or it will be necessary to strain the lamps when a few are used, in order to have normal brilliancy when a number are desired. To still further complicate matters, the E. M. F. is higher at the start, particularly if only a few lamps are "on" than it is later in the evening. These differences in E. M. F. are small but are sufficient to vary the candle-power of the lamps.

If, therefore, each customer is connected with one or more batteries for his sole use the following takes place: As darkness approaches one or two lights are turned on and are raised to abnormal candle-power straining lamps and making consumers dissatisfied with any less light later on, and as the customer's eyes become tired the light drops, possibly not below the normal candle-power but the *comparison* is bad and it requires considerable power of persuasion on the part of the company's "talker" and loss of his time as a "worker" to make the customer believe that his eyes are at fault and not the light. It may be that an entertainment is given in the house, and then the drop of candle-power is more noticeable, although it may not fall much below the normal.

Of course it is possible to design mechanism to overcome all such troubles, to throw in extra cells and extra batteries as required, etc. To design mechanism to accomplish such work with reliability and which will not be too costly for maintenance or prohibitory on account of excessive first cost is considerable of a problem. Matters are further complicated by the necessary use of charging mechanism. Also, it is desirable to have switches so arranged that it will be impossible to have charging current "on" when lights are being used *from* a battery. The writer has run 1,000 lights in such a manner (with charge on) for over a year, but does not advise it from any standpoint except necessity.

If a few large stations are used the E. M. F. at same can be readily shown at main station, and regulated from same if desired, or an attendant can be sent to any station needing regulation.

My experience teaches me that if batteries can be charged under inspection and allowed to have a discharge without excessive variation in amount of same, that the batteries will give *much more reliable* results than in any other way. The nearer this can be approached the more satisfactory will be the service.

If, therefore, it seems to be advisable in any city to erect a storage battery system for general distribution, I believe it will be found best to erect a very few large battery stations at the various centres, and that the interest on the extra cost of the wire leading from the same to the lamps, over what would be necessary if each light were close to a battery, will be far more than saved in the lessening of attendance alone; and that the avoidance of other evils I have mentioned will thus be clear gain.

CHEYENNE, WYO., April 5th, 1887.

LEAD-ENCASED CONDUCTORS.[1]

BY DAVID BROOKS.

IN the first attempt in this country to work electric telegraphy by Prof. Morse, the wires were covered with cotton, soaked in a preparation of shellac, drawn into lead tubes four together, the intervening space being left empty.

This system was laid from Baltimore towards Washington, about five miles on the Baltimore and Ohio Railroad. I got this information from Tatham & Bros., who made

1. Paper presented to the American Institute of Electrical Engineers May 18, 1887.

Digitized by Google

most of the lead pipe purchased, although none of what they made was laid.

The experiment was a failure. About that time, or a little before, Prof. Jacoby, of St. Petersburgh, undertook to lay cotton-covered copper conductors in lead pipe with the intervening space filled with rosin. There have been very many attempts of that kind which proved to be failures, until the year 1856, when the discovery of petroleum brought paraffine into the market as a cheap commercial product. This was brought to my notice, and I made many experiments to test its insulating properties and as the result, it was taken to the patent office, and the patent awarded me, broadly, for its insulating properties.

It occurred to me that cotton-covered wires could be drawn into lead pipe and a useful system for underground purposes accomplished, but before rushing to the patent office, specimens were buried in the yard of my factory directly under a body of water, or earth soaked with water from a hydrant. These experiments were repeated, and for a long time were attended with failure. In the journal of the *Society of Telegraph Engineers*, published in London, we find accounts of similar experiments made there with like results.

Sealing the ends of a portion of this leaded cable, coiling it up, immersing it in melted paraffine, and raising the heat to about the boiling point of water, we noticed bubbles coming out apparently from the lead. Continuing this heat until all bubbles ceased to rise and then testing the cable, we found the insulation restored. The inference was brought to my mind that the coiling and the uncoiling of lead produced such molecular changes in the metal as to make it sufficiently porous, to admit moisture, and the many unsuccessful attempts to lay lead-covered cables, when the cables were insulated with paraffine, in deep water have served to strengthen this impression.

It must be borne in mind that paraffine, rosin, asphalt and other similar substances in their normal condition are brittle and the coiling and uncoiling of the lead pipe breaks them into innumerable small particles, which would leave the cable full of cracks or crevices.

These circumstances suggested the use of oil, and that brought out my system of iron tubes on account of their cheapness.

Lead-covered cables are now successfully made by having the insulating material either rosin, asphalt, or pitch, mixed with oil in sufficient quantity to make the material plastic and capable of being bent without fracture.

Some of the inventors of these mixtures have repeatedly stated that their insulating material is a secret. Other materials are the subjects of patents.

Asphalt, rosin, or pitch, when mixed with oil sufficient to make them plastic but not to crack, is heavier than water, and thereby a great advantage is gained. Paraffine, either solid or liquid, is lighter than water. If solid, it cracks—if liquid, a drop of water penetrates it by reason of greater specific gravity of water.

In pursuance of the foregoing remarks we must now look at the advantages of lead-covered conductors for all kinds of indoor purposes, or what are commonly called distributing purposes for electric lighting, etc.

An ordinary cotton-covered paraffine conductor for inside work is a dangerous thing. There has been sufficient property destroyed by the use of these cheap articles to pay five-fold the substitution for them of lead-covered conductors.

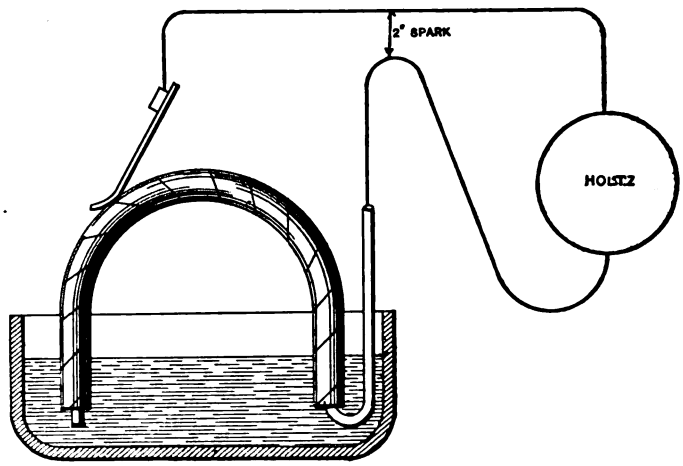
A lead-covered conductor, No. 18 gauge, may show an insulation resistance of 10,000 megohms per mile. When used for inside telephone purposes, if the lead covering is attached to a gas or water pipe, there is perfect safety from fire from the electric current, should the outside conductor come into contact with an arc light conductor.

A copper conductor, No. 00, for arc lighting can easily be insulated when lead encased to 500 megohms per mile, and when that is brought into a building for distribution purposes, and the lead covering connected with a water or gas pipe, there is perfect safety from fire from the electric current, such as occurred at the Temple theatre in Philadelphia. Again, we can scarcely see how persons could be injured by the electric current conveyed through an insulated conductor covered with lead pipe, as was one of the employés of the Brush company in this city, who was killed not two weeks ago, and, since then, as another person was killed in the Adams Express building in New York.

Mr. J. N. Miller, of Cincinnati, has referred to several instances where people have been killed by taking hold of the electric light conductor covered with what is known as the underwriters' insulation, which is simply no insulation at all when exposed to dampness. As this insulation cannot be made to burn with a lighted match, it has been supposed to possess great elements of safety. But when it is encased in lead, and used for incandescent or arc lighting, a great portion of the current passes through the "insulation" to the lead covering.

Taking a piece of this underwriters' wire, covered with lead, and testing the insulation from conductor to covering with a current from a Holtz machine, you can produce no disruptive discharge, because the current passes through the "insulation" quickly, as fast as you can generate it by the machine. Take a similarly constructed lead-encased cable, properly insulated, immerse both ends of it in the insulating mixture and pass a current from the Holtz machine through naked conductors through the air,

Fig. 1



one pole connecting with the encased conductor and the other with the lead covering, a spark two inches long will pass between the two conductors in the air before any passes between the casing and the conductor, although the distance through the insulation is only one-eighth of an inch. The object of immersing both ends of the encased cable in the insulating material is to prevent short circuiting through the air from copper conductor to lead covering at the terminals.

Much has been said of the incombustibility of the underwriters' insulation. But it is no more incombustible than the proper insulation, provided the spark is not exposed to the air. We can make a disruptive discharge through the insulation if it be too thin, but no combustion takes place, because the air is excluded.

We can now compare this insulation with gutta-percha, caoutchouc, and their compounds.

Exposed to the air, a lead-covered conductor will last ten times as long. Besides this, when running these seam-covered conductors around right angled corners, the insulating covering is apt to open upon the outside of the bend, while a lead-covered conductor will bear much rougher usage.

This quality has been demonstrated by a lead-covered

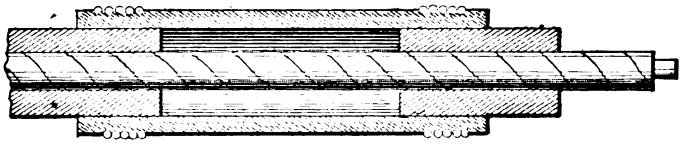
Digitized by Google

cable for telephone and telegraph, armored with iron wire, and laid across the bottom of the river Delaware between Philadelphia and Camden seven years ago, where it has worked without interruption or deterioration for all that time, although occasionally hooked up by anchors and doubled upon itself.

Other cables laid in the same locality have had frequent interruptions; some have been entirely destroyed and replaced by similar ones, which have perished in their turn, and, for aught I know, the process is still going on. However, there is another class of electricians coming upon the stage who do a little of their own thinking, and they have found out that there is both economy and good service attained by more recent devices.

There has been one objection to these lead-encased conductors, that the space *at the terminals* between the casing and the conductor is so short that when exposed to a damp atmosphere moisture collects upon the surface of the unprotected insulating material, and thus the insulation of the conductor is impaired. Messrs. Tatham & Bros. have a simple device by which that difficulty is completely remedied. A short section of the lead casing is cut

Fig. 2



out some inches from the terminal and an India-rubber sleeve slipped over the gap, and over both parts of the lead pipe remaining. Both ends of the sleeve are then tightly bound to the lead pipe with twine, and the insulation of the cable is safe from moisture.

THE EFFICIENCY OF SMALL ELECTRO-MOTORS.[1]

BY H. E. H. CLIFFORD, S. B.

THE following tests of electro-motors are presented as giving a good example of the efficiency of some of the smaller motors in use at the present day. They have been exclusively devoted to the determination of efficiencies, the subjects of governing and of smoothness of running under different loads being left out of consideration. The only other series of tests which have been published in this country, so far as I have been able to learn, are those made on motors and dynamos at the International Electrical Exhibition held at Philadelphia in 1884.[2]

The tests have been carried on in the Physical Laboratory of the Massachusetts Institute of Technology, during the years 1885–86, by Messrs. F. A. Pickernell, H. G. Pratt, D. P. Bartlett, and the writer,—students at the Institute.

The number of machines tested was thirteen. I give below their names, together with either a brief description of their peculiarities or a reference to some publication in which they are described.

Griscom (S. P. Thompson's Dynamo-Electric Machinery, 2d Ed., p. 429).

Ayrton & Perry (S. P. Thompson's Dynamo-Electric Machinery, 2d Ed., p. 432).

Gramme-Machine à petite lumière (S. P. Thompson's Dynamo-Electric Machinery, 2d Ed., p. 120).

Magneto Gramme (S. P. Thompson's Dynamo-Electric Machinery 2d Ed., p. 117).

Thompson (S. P. Thompson's Dynamo-Electric Machinery, 1st Ed., p. 354).

Deprez (Prescott's Dynamo-Electricity, p. 707).

Monarch.—An electro-magnet revolving within a ring-shaped electro-magnet, making use of consequent poles. The ordinary split-ring commutator is used.

Cleveland.—The armature, made up of two shuttle wound armatures mounted on the same shaft, but placed at right angles to each other. This armature revolves in a strong field produced by two field magnets, wound so as to have consequent poles at their middle. Instead of brushes, four anti-friction rollers are used in connection with a four part commutator. The pressure of the rollers is adjusted by springs.

Model Edison Dynamo.—A miniature machine of the Edison patent, but series wound instead of shunt wound.

Diehl.—The field magnets are hinged at the yoke, so that the distance of the pole pieces from the armature is capable of adjustment. The armatures are made up of two Siemens shuttle wound armatures at right angles to each other on the same shaft. The motor is shunt wound. Two sizes were tested.

Hill.—The field magnets are placed below the armature, which revolves between cast-iron pole pieces. The armature consists of a series of eight spools of wire arranged in couples, the axes of adjacent couples being at right angles to each other. The motor is series wound. Two sizes were tested.

The efficiency of a motor is equal to the horse-power delivered, divided by the rate of consumption of electrical energy by the motor. That is, if HP = horse-power delivered, C = current in amperes, E = electromotive-force in volts, as measured at the terminals of the machine,

$$\text{Efficiency} = \frac{HP}{\frac{CE}{746}}$$

The instruments used in the determination of C and E were Sir William Thomson's current and potential galvanometers. These had previously been carefully calibrated, and found to be correct to within 0.2 per cent. in the positions at which they were used in the tests. In cases where the compensating magnets had to be used, their intensity was carefully determined on each day of use, so that no material error should be introduced from this source. As far as possible, however, the use of the magnets was avoided.

For measuring the power given out by the smaller motors, a raw-hide belt or a cotton cord was passed completely around a brass pulley on the motor shaft, the upper end being attached to a spring balance and the lower to a scale pan. By varying the weight in the scale pan the speed of the motor could be changed.

A Chatillon balance weighing to ½ ounce was used. In the tests on the magneto-Gramme and the Gramme, "à petite lumière," the machines were placed on a cradle dynamometer, a modification of the form devised by Prof. Brackett, of Princeton, and a dynamo machine was used as a friction brake. By closing the circuit of the dynamo through greater or less resistance, the work done, and consequently the power absorbed by the brake, could be varied.

In testing small motors great care must be taken in measuring the speed accurately. In these tests the speed indicator from a small siren was used. This was connected to the motor by an endless band passing from the pulley on the motor shaft to a pulley of the same diameter on the siren. The power required to run this indicator was excessively slight, and in computing the work done was neglected. The slip of the belt was negligible, as shown by numerous tests. With the magneto and Gramme, "à petite lumière" a continuously recording engine counter was used, connected to the motor by means of a flexible spiral spring.

The following table gives, in parallel columns, the names of the motors tested, the current in amperes, the electromotive-force in volts at the motor terminals, the activity

The table preceding gives the tests in full, made on the model Edison dynamo, and illustrates very well the relation of speed and efficiency. This machine is built somewhat after the style of the old Edison Z machine. It is series-wound, and has about the resistance, hot, of an Edison incandescent lamp, old style. The dynamo is an exceedingly neat and smooth running machine. The motor runs without vibration and with no sparking, and heats up but very little, even at the highest speeds. It has been run for two minutes at a speed of 10,000 revolutions per minute. The great speed here obtained by such simple means, together with the readiness with which it can be varied within wide limits, indicate the availability of such a motor in any physical experiments in which a great speed of revolution is needed, as in studies of the velocity of light, the duration of the electric spark, etc.

TABLE III.

Name of Motor.	Weight in pounds.	Maximum horse-power delivered.	Horse-power per lb. weight.

Hill, No. 1	7.0	.0120	.0017
Hill, No. 2	16.0	.0374	.0023

One of the chief advantages derived from the use of electromotors is the small weight per horse-power developed. The motors, which we have tested with one exception, the Gramme machine, "à petite lumière," have been intended for doing any light work, and the efficiency exhibited is not, of course, nearly as high as would be shown with larger machines. Activities varying from 1.31 h. p. to .004 h. p. have been obtained, with efficiencies varying from 84.5 per cent. to 10.1 per cent. Professors Ayrton and Perry in their paper on "Electro-Motors, and their Government" (*Journal Society of Telegraph Engineers*, 1883), state that motors may be constructed to deliver one h. p. per 100 lbs. of dead weight. Table iii. shows the horse-power per pound weight of the various motors tested, and in no case does it rise as high as 0.01 of a h. p. Their own motor, as will be seen by referring to the table, gives but 0.0045 of a h. p. per pound of dead weight. In the most efficient machine tested, the horse-power delivered per 100 lbs. dead weight of machine falls a little short of 0.8 of a h. p. I think that for moderately small motors, about 300 lbs. per h. p. would be a closer figure, although with larger motors this would of course be considerably reduced.

ROGERS LABORATORY OF PHYSICS, March, 1887.

A FEW COMPARATIVE STATISTICS OF ELECTRIC RAILWAYS.[1]

BY T. COMMERFORD MARTIN.

IT is not now my intention to present a paper on the general subject of electric railways. That I did at a meeting of the Institute held last December, when I was enabled to offer a few statistics on the electric railway as compared with horse, cable and other methods of traction for street cars. I have found since then a great desire generally for information as to the status of electric roads in the United States and Europe. Street railway men, investors and others have wished to know whether such a thing as an electric road was really operating anywhere or not, and, if the lines were running, what the cost of construction and operation was. The tables I submit herewith are intended as an answer to those queries. It has been difficult to get at a common basis of estimate and statement. With regard to the European roads, I would say that I have been greatly indebted for the figures to a most admirable and exhaustive paper, read a few weeks ago by Mr. Anthony Reckenzaun before the London Society of Arts. In Europe, as here, various systems of transmitting the current and of connecting up the motor with the car axles and wheels are in use, and, as yet, no determination as to the best method seems to have been reached.

Respecting the figures for this country, I would say that they are necessarily very much in the shape of an estimate as to the number of passengers; though, by allowing each car only 50,000 passengers a year—merely 150 a day—my calculations come out as rather low. The facts may be summed up by saying that in Europe the electric railways are now carrying passengers at the rate of 3,000,000 annually. In America they are carrying at the rate of over 3,500,000, and when the roads now building are finished—to say nothing of the scores for which contracts are being made—the number carried will be at least 7,000,000 annually. When the roads at the places I enumerate in the tabular foot-notes all go into operation, the number will be easily quadrupled. As to cost, I would remark that in every instance yet brought to notice, electricity has spelled economy. I saw recently some authentic and extremely elaborate statistics for 1879 of street railways and their cost in New York and Brooklyn. They were taken from the various official reports. The showing for the total cost of operation per car ranged between $8 and $10 per day at that time. The saving on that with electricity is, according to circumstances, at least 25 to 40 per cent. with heavy traffic. I have provided copies of the following tables for distribution among the audience and need not read them.

1. Read before the American Institute of Electrical Engineers, May 18th, 1887.

New Roads.—A special charter has been granted by the Austrian Government for a road in the Austrian Alps to cost about $350,000, and to be 15 miles in length.

A road is being built in the great salt mines at Stassfurt, Germany.

The North Metropolitan Tramway Company in London has several motors now ready for use with storage batteries, on its line, awaiting powers from Parliament.

ELECTRIC RAILWAYS IN AMERICA, MAY, 1887.

Place.	Length.	Motors and Motor cars.	No. of passengers.	Freight.	Expense of operation.	Car miles run.	System of Conductors.	Prime power.
*Baltimore, Md., 1885	2 miles (single track with turn outs).	6	260,000 yearly.	.....	$4 per car per day.	Each motor runs 73 miles daily.	Third rail and overhead wire.	Steam engine
*Los Angeles, Cal. 1887...	3 miles, single and double.	8	200,000 yearly.	.....	.....	....	Single and doble overhead wire.	Steam engine
*Port Huron, Mich., 1885-6,...	4 miles, single track.	8	275,000 yearly.	... .	.....	....	Single overhead conductor.	Steam engine
*Windsor, Can., 1885.....	Nearly 2 miles, single track.	2	200,000 yearly.	.....	$4 per day for power	64 miles each car per day	Single overhead conductor.	Steam power from electric light station.
*Highland Park, Detroit, Mich., 1886..... ..	3½ miles, single track.	2	200,000 yearly.	.....	80 cents per day for fuel.	Each runs 13 h'rs daily; capacity, 30 passengers; speed, 15 miles an hour.	Sunken central rail.	Steam engine
*Dix Road, Detroit, Mich.,1886	1½ miles, single track.	4	300,000 yearly.	.....	.....	The trains run from 6 a. m. to 11 p. m.	Double overhead conductor.	Steam engine
*Appleton. Wis., 1886.....	4½ miles, single track & dble.	8	400,000 yearly.	.....	For power, wages of one man as they own their own water power.	17 hours daily.	Double overhead wire.	Turbine within wheels.
*Scranton, Pa., 1886.....	3½ miles, single track, four sidings.	3	300,000 yearly.	. .....	$9 per day for power, but are putting in their own engine.	Each car runs 85 miles per day.	Overhead wire.	Steam power from electric light station.
Denver, Col., 1886	3½ miles, single and double.	7	500,000 yearly.	....	$1.50 per day for fuel.	....	Conduit for series system.	Steam engine.
Montgomery, Ala. 1885-86.....	11 miles, single and double.	18	This ran 2 cars one year. Have just started other cars. (1,000,000 yearly).	....	Fifty per cent. less than horse and mule traction — General Manager's report.	....	Overhead conductor.	Steam engine.
†Kansas City, Mo.	.....	. .....	.....	....	....	....	.....	.....
Orange, N. J., 1887..... ...	½ mile built.	1	. . ..	.....	... .	.....	Overhead conductor.	Steam engine.
Boston, Mass. (sugar refinery), 1887.....	Short track within the works.	1 locomotive, 3 cars.	....	The cars in constant use all day; the loads averaging 10 tons per trip, and each round trip averaging 5 minutes	... .	... .	Overhead conductor.	Operated from the lighting dynamo.

* Extending line or increasing rolling stock. † No specific details received, line not being yet in regular operation.

New Roads—Electric railways are now in course of construction, or under contract, at Pittsburgh (3 roads); Los Angeles; Binghamton, N. Y., 4½ miles, 8 motor cars; Lima, O., 3 miles, 6 cars; San Diego, Cal., 9 miles, four 40 h. p. motor cars; Ansonia, Conn., 3½ miles (water power); New York city (for Fulton street) St. Joseph, Mo., 20 cars; Mansfield, O.; Ithaca, N. Y.; Harrisburg, Pa.; Woonsocket, R. I.; Richmond, Va., 40 cars, 11 miles of track.

Companies have been formed or steps taken to build and operate electric roads at Flushing, L. I. (2); Lincoln, Neb; Brookline, Mass. (2); East Cambridge, Mass.; Newton, Mass.; Boston, Mass.; Asbury Park, N. J.; Pelham Park, N. Y.; New Brunswick, N. J.; Plainfield, N. J.; Bayonne, N. J.; Worcester, Mass.; Scranton, Pa.; Carbondale, Pa.; Philadelphia, Pa.; Reading, Pa.; Bangor, Me.; Biddeford, Me.; Westfield, Mass.; Chicopee, Mass; Muncie, Ind.; Gratiot, Mich.; Tiffin, O.; Cincinnati, O.; Brooklyn, N. Y.; Coney Island, N. Y.; Rockaway, N. Y.; Winston, N. C.; Jacksonville, Fla.; Pensacola, Fla.; Birmingham, Ala.; Selma, Ala.; Atlanta, Ga.; Fort Smith, Ark.; Wichita, Kan.; San Francisco; San Jose, Cal.; Newton, Kan.

ABSTRACTS AND EXTRACTS.

ELECTRIC LOCOMOTION.

The *English Mechanic* of April 29th, publishes an abstract of Mr. A. Reckenzaun's very interesting and instructive paper on Electric Locomotion, read before the Society of Arts, April 20th, as follows :—

The author said it seems an easy thing to the uninitiated to reduce 800 revolutions of one shaft to 80 of another ; but when it has to be done in connection with the tramcar, a vehicle on which space is limited, noise objectionable, and dirt and dust in abundance, one obstacle after another crops up to disappoint the inventor who imagines he has solved the problem. On the Berlin-Lichterfield line one of the cars has run 76,000 miles since the opening, and has pulleys on the motor shaft and car axles with V-grooves in which run cords of spiral steel wires. The cords are made by winding a pair of wires closely on a mandrel rather less than one-eighth inch in diameter, so that the finished "cord' is a flexible spiral having an external diameter of barely 7-32 of an inch. This device, it seems, works without noise or vibration, though some little difficulty is experienced in adjusting the "cords" upon the pulleys ; for if too tight they will break at the joints, and if too loose slip at starting—not a disadvantage, as that is the most trying moment in all gearing driven by electromotors. Other devices are employed, such as the pitch-chain, but the spiral cords seem to be the best. On Mr. Volk's line at Brighton, belts made of leather links are used ; the armature shaft, with a 5 inch pulley, driving a countershaft with a 24 inch pulley, from which the belt is taken to the driving axle. The belts slip a little at starting, but that eases the motor ; while, if necessary, the countershaft being carried in adjustable bearings, the belts can be made as tight as desired. The expense per car mile of this line, the prime mover of which is a gas engine using gas at 3s. 3d. per 1,000 cubic feet, is only 2d.—a figure which is below that which Mr. Reckenzaun gives as possible when the most efficient machines are employed—viz., 3d. The Brighton arrangements are, however, scarcely suitable for ordinary tramcar traffic, as there is no mud to contend with, and the ordinary rails serve as conductors of the current. It should also be noted that each car last year made no fewer than 23,475 miles, and but for opposition in certain quarters the Brighton electric tramway would be a success in every sense of the term. Of lines worked by overhead conductors the most carefully constructed, if not the most important, is that arranged on the plan of Messrs. Siemens and Halske at Mödling, near Vienna. It is nearly three miles in length, and, like most other electric tramways in Europe, does nine-tenths of its traffic between April 1st and the end of October, the average cost being 3.42d. per car mile. The average speed permitted is a little over nine miles an hour, and the conductors are slotted tubes carried on posts 18 feet high and 90 feet apart, except on sharp curves. The bore of these tubes has to be made perfectly smooth, so as to offer but little resistance to the passage of the contact carriage, which consists of a flexible piece of flat steel carrying three gun-metal pistons made in halves, with springs in the middle, so as to keep the surfaces of pistons and conductor in contact. The pistons require renewal about every two months. Overhead conductors are, however, scarcely suited for electric tramway work, except in country districts, such as the line just referred to, or that between Frankfort-on-Main and Offenbach, which is 4.1 miles long, and has the slotted overhead tube, and a contact carriage made up of two solid iron pistons, which require renewal every three or four weeks at a cost of one shilling for each carriage. Both the Mödling and the Frankfort cars have spur gearing, and the experience gained with them is not favorable to the further utilization of that means of connecting the motor shaft with the driving axles. For instance, in the Frankfort cars a pinion of 17 teeth on the motor shaft gears into a wheel of 56 teeth on a countershaft, and a pinion of 26 teeth on that drives a wheel of 52 teeth on the axle of the car, giving a ratio of about 6.6 to 1 between the motor and the car wheels. The motor, however, runs at the comparatively low speed of 500 revolutions per minute, and the whole arrangement is heavy, for the train of wheels weighs about 4 cwt., and the total weight of the driving gear for one car is more than 26 cwt. The gearing produces so much noise and vibration that the sensation experienced in the car is anything but agreeable, and the wear and tear are so great that the pinion on the motor shaft wears out in a month, although made of hard gun metal. Mr. Reckenzaun says that one of the cars is being fitted with wheels having double helical teeth, which are expected to work more smoothly and be more durable ; but it may be doubted whether any difference in the shape of the teeth will render toothed gearing tolerable, although it should be mentioned that nearly one million passengers patronized the Frankfort electric tramway last year in spite of the disagreeable noise made by the gearing. On the Port Rush line, the longest electric tramway in the world, pitch-chain gearing is used, and is stated to work satisfactorily, as it does also on the Bessbrook-Newry line. Both these lines are worked by electricity derived primarily from water power, and the cost is respectively 3d. and 4d. per car mile, in the latter case including everything. Mr. Reckenzaun referred briefly to the Blackpool line, and mentioned the systems devised by Profs. Ayrton and Perry, and by Messrs. Pollak and Binswanger, the former having the "third rail" divided into sections, the connection with the main cable being made automatically by the train as it moves along ; and the latter an altogether novel system, in which a powerful magnet under the car attracts, or is supposed to attract, an iron armature in a thoroughly insulated trough beneath each rail section, which armature when attracted makes contact between the cable and the surface rail, and through the latter with the switch of the car motor. Both systems are ingenious and worth trial ; but at present no opinion can be formed of their efficiency, as they exist only on paper. So far, we have referred only to lines in which the current is conveyed from a central station to the car throughout the whole length of the tramway ; but batteries carried by the car itself are a much earlier device, having been adopted so long ago as 1839, when, of course, they were too expensive, the secondary or storage cell not having come into knowledge then. In order to compare the two systems, Mr. Reckenzaun estimates the efficiency of the conductor and of the secondary battery in the following manner. Taking the tramway at Mödling, the conductor has two ohms resistance, 20 amperes of current for each car, and 500 volts E. M. F. at the terminals of the charging dynamo. Supposing only one car running on the line, the waste of energy will be practically nothing at the commencement of its journey ; but it will be $20^2 \times 2$ when it approaches the furthest end of the line ; the average resistance—that due to half the length of the conductor —is 1 ohm, therefore, the average loss is only $20^2 \times 1 = 400$ watts against $500 \times 20 = 10{,}000$ watts generated by the dynamo, or a loss of four per cent. With six cars on the line equally distributed, however, using 120 amperes, the loss will be 14,400 watts out of 60,000, or 25 per cent.; and so by increasing the number of cars and the current the efficiency becomes less and less. With the accumulators the loss is constant, no matter how long the line, provided the quantity of stored energy is sufficient for the time, and it matters not how many cars run at the same time on the tramway. The weight to be propelled would be increased, which would entail a corresponding augmentation of power, and therefore a greater consumption of fuel would be the result. But fuel really plays a small part in the total expenditure, and viewed from the standpoint of convenience the propulsion of tramcars by means of secondary batteries is the best system that can be adopted, especially in towns, because it leaves the permanent way in its present simple state. Whether each car should carry its own battery and motor, or an electric locomotive should be used for hauling cars, will depend on circumstances ; but so far as the neighborhood of London is concerned, it appears that the electric locomotive will be the first system tried, for trips have already been made with the Elieson locomotives on the Romford road out of Stratford, and we presume they will soon be put into regular work. The locomotives and the socondary batteries are ready, and but for the roundabout methods of the legislature would have been earning money and conveying passengers long ago. These locomotives weigh "roadworthy" something like seven tons ; what they will do in the way of hauling cars remains to be proved, but there is not much doubt that they will be cheaper than horseflesh, and it is certain that they will leave the road as clean as they found it—a point which should not be forgotten in comparing the respective merits of horse and mechanical traction. Sufficient has already been done to show that the cost of electric tramways need not exceed 4d. per car mile, whereas horses cost from 7d. to 10d.; so taking the lowest estimate there is a saving of one-half, and probably when experience has enabled managers to rub off items which can be dispensed with, the economy may be still more. As to the gearing for transmitting the power, Mr. Volk believes in the linked leather belts, but Mr. Reckenzaun and others consider the worm arrangement the best ; on this point the mechanicians may have something to say, for if electric tramcars are to be introduced it will not be either the noise or the vibration produced by the gearing that will long remain an objection. It may be that the spiral wire cords adopted and used for some time on the Berlin line will be found the best arrangement ; but it is certain that spur gearing will not do, because, however smoothly it may run when new, it rapidly deteriorates and makes so much noise as to be decidedly objectionable. If the electricians can, however, place electric tramcars on our roads, the gearing will not long be a source of trouble to them, for there are many methods of transmitting motion which are free from noise, which only await a favorable opportunity for asserting their superiority.

ELECTRICITY FROM ATMOSPHERIC OXIDATION.

When a sheet of copper is kept out of direct contact with air by being immersed in ammonia solution, oxidation

Digitized by Google

of the metal is gradually effected by virtue of the dissolution of oxygen from the air at the surface of the liquid and diffusion of the oxygen solution to the vicinity of the copper. This action can be materially accelerated by arranging horizontally on the surface of the fluid a plate of platinum or other electrically conducting material not chemically acted on by the liquid and connecting this by means of a wire with the copper plate. Dr. C. R. Alder Wright, F. R. S., and Mr. C. Thompson, F. C. S., have succeeded in producing a voltaic cell on this plan. The upper conductor or aeration plate being simultaneously in contact with the atmosphere and the liquid, attracts to its surface a film or ama of condensed gases, the oxygen of which becomes gradually transferred to the copper, and a voltaic current circulates in the wires. Cuprous oxide is formed in the solution of ammonia in contact with the copper plate. Other combinations of the sort have been tried by Dr. Wright and Mr. Thompson, and some of these yield currents sufficient to produce measurable amounts of electrolytic decomposition outside the cell. —Glasgow *Engineer*.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Shall we Have an Electric Railway Boom.—Bidding for the Asbury Park Franchise.—The New Orange Valley Enterprise.—The Cross-town Railway in New York.—Fatal Dynamo Accident.—Newark's Pony Messenger Service.—A House for the Electrical Engineers.—Competition for City Electric Lighting.

PUBLIC familiarity with electric railways will rapidly follow the actual introduction of this improved method of transit, and it is by no means improbable that it may result in a "boom" in the course of a year. There is certainly considerable satisfaction in conducting a railway business having a remunerative traffic, if we may judge from the remarks of a gentleman who has recently started one partially equipped with an electric plant. There are, he said, no cutting of rates, no trade discounts, no bad debts, no bills to collect where we "will send a check next week" or "the proprietor is out of town." Expenses are known to a dollar, and your revenue comes in complete every day. If your enterprise is going to pay at all, it pays from the beginning.

There has been a little competition at Asbury Park, N. J., in bidding for a franchise for a street railway at that noted summer resort. The Daft company bid $2,300 per annum for a 10 year term and $3,000 yearly for 20 years. The VanDepoele company offered five per cent. on the gross earnings annually, provided they exceeded six per cent on the investment. In case they fell short, one per cent was to be deducted for each one per cent. short in the income. The differing methods of bidding evidently threw the burden of agony back on the commissioners, who have not as yet been able to decide which proposition is the most profitable to the public. As the road is to be started July 1st, something will have to be done soon.

The experiment which is being conducted on the new Orange Cross-town and Orange Valley railway, to convince the authorities and the people that the electric motor is not an obnoxious thing, is doing very successful missionary work. Passengers at once appreciate the improvement in electric lighting over the consumptive kerosene lamps ordinarily used on street cars. If the successful operation of this road actually overcomes the conservatism of a Jersey councilman, great progress will have been made already. It appears probable that this will be the case, and that the opposition of property holders to the planting of poles will be the only remaining obstacle. Possibly the financial success of the enterprise will warrant avoiding this difficulty by the adoption of storage batteries.

The public advertisement of the North and East river railway franchise in this city, contains the following clause:

Sixth—The plans upon which this North and East river railway shall be built and operated are those of the Bentley-Knight Electric Railway Co., and are described as follows: The plant consists of a stationary source of power, engines, boilers and dynamo-electric machines, which may be located at an extreme end of the line, at tide-water or at a station; a conduit running from the source of power to and along the whole length of the line, containing stationary and permanent conductors, which shall receive and distribute the electric current to the motors placed under the cars and geared to the wheels or axles, and a depending conductor, which, passing through a slot in the conduit and sliding in contact with the stationary conductor, maintains unbroken connection with the source of power.

One of those fatal accidents which frequently arise because of the familiarity of employés with dangerous apparatus, recently occurred at the Adams Express Co.'s building, No. 59 Broadway. John H. Simpson, the night engineer in charge, while showing the dynamo to a friend, recklessly placed himself in contact with an exposed portion of the apparatus, which resulted in his almost instant death. He came from Philadelphia where he had had considerable experience in electric lighting.

Newark being a city of magnificent distances, the prompt delivery of telegrams has always been a serious problem, while its rapid and frequent railway communication with New York, has made delay in telegraphic communication all the more apparent. If a man can make a certain trip personally by railroad including a good walk at each end, in an hour, he will naturally growl if a telegram requires two hours to cover the same distance. The telephone has been used with considerable success in Newark, to avoid the delays in the ordinary messenger service. Manager Feary, of the Western Union office is now, however, divorced from the telephone business, and has introduced a pony express delivery. This certainly has one advantage, it will be fun for the boys, even should the customers not like it. Whether the boys will take the shortest route, or indulge in dashes over the most popular streets, is a question to be determined only by experience. The ingenuity of the average messenger in finding good reasons for not doing what he ought, is one of the most serious obstacles to the efficiency of telegraph service.

The American Institute of Electrical Engineers, which has quietly pursued its course for three years past in nurturing the growth of electrical science, has suddenly come to the front with a determination to buy a house, and become one of the recognized public institutions of the city. The mere fact that other organizations own houses, has proved an incentive for the Institute to undertake a similar enterprise, and consequently gain that character for stability which naturally attends the acquirement of real estate. As there is nothing of the kind in existence in the city, while the number of people interested in electrical research is increasing very rapidly, there appears to be every reason to believe that success will crown the undertaking, and it will certainly add to the public appreciation of electrical work.

There has been an unusual amount of dickering over the city electric lighting for next year. In spite of the supposed demand of the public for the wires to be placed underground, this has been lost sight of, in the anxiety to profit by the competition between the various companies who are anxious to get in. The old companies have, in many cases, bought their experience at a pretty high price, while some of the new ones have profited by it. Altogether, the unseemly strife for the contracts does not seem to be very encouraging to those who expect soon to be obliged to bury their wires and furnish lights at the lowest price prevailing in the rural districts.

NEW YORK, May 26th, 1887.

PHILADELPHIA.

Continued Construction of Pole Lines in Philadelphia.—Delay of Councils in Enforcing Underground Ordinances.—Another Law Suit Concerning the Chopping of Bankers and Merchants' and American Rapid Wires by the Western Union Co. Two Years Ago.—Suit of the Edison Co. against the Keystone Electric Light Co. for Infringement of Patents in Philadelphia.—The New Jersey Southern Telephone Co.—New Underground Conduits for the City's Electric Lighting.—Electric Transmission of Power Between Harrisburg and Steelton.

WHILE the people and city councils have been clamoring for the removal of all over-head telegraph, telephone and electric light wires, the city itself is aiding in the continuation of this dangerous nuisance, as it permitted the erection of 371 additional poles and the stringing of 226 fresh miles of wire during last year. Of this number private companies are responsible for planting 231 poles along the streets, and loading them down with 122 miles of telegraph and telephone and 47 miles of electric light wires, while the city's electrical department erected the remainder of the poles and wires. There are already 8,870 poles and 5,289 miles of wire blocking the streets of Philadelphia, and chief of the electrical department Walker says there will be 300 new poles pointing skyward before the end of this year. The Northern Electric Light Company is now planting about 100 new poles along East Girard avenue, second street from Germantown road to Diamond, and other streets in the northeastern part of the city.

Councils first began its crusade against poles and over-head wires in 1882, and several times dates were fixed for the compulsory burial of these troublesome wires and the removal of the poles from the streets, but the power of the telegraph, telephone and electric light companies has been such that councils always receded from their position.

Chief Walker says that the increase in poles is mainly due to the extension of the electric light service for lighting the public highways. There was a general ordinance passed in 1885 allowing the electric light companies to erect poles at will, without asking Councils' permission, providing that the same should be used exclusively for electric lighting. It would seem that the companies could easily take advantage of this generosity of Councils to use the poles for furnishing lights to private parties along the routes of the lines used for city lighting, but chief Walker says he does not know of any instance where this advantage has been taken by the companies.

Digitized by Google

Chief Walker declares that he will heartily aid Councils in any effort they may make in trying to secure the removal of the poles and wires. Worse than all else is the failure of these companies to pay the meagre license charges that the city has sought to collect from them for the privilege of using the streets. During the past year the city charged the companies $23,213 for attachments to city poles and maintenance of overhead poles and wires and underground conduits and wires, but the companies only saw fit to pay $7,008.50, and chief Walker has been compelled to place the other bills in the hands of the city solicitor for collection. The most striking examples of this indifference are the Bell Telephone and Western Union Telegraph companies. The former was assessed $6,163, but only paid $1,398.59, and the latter was assessed $3,274, but only enriched the city treasury by $26.50 of this amount. The Mutual Union Telegraph Company, a creature of the Western Union, remains indebted to the city $1,615 and the Bankers and Merchants' Telegraph Company $1,476.

In this connection chief Walker says that the city ought to begin to establish its own plant for the lighting of streets with electric lights. Philadelphia now has 500 public electric lights, but this number will soon be increased to 526. As the average price per light is 54 cents a night, the total cost of maintaining these lights is $107,674 per annum. In reference to this matter the head of the electrical department says:

"The lighting of our public thoroughfares by electricity has reached a point which I think would justify the city in establishing its own plant for that purpose; the city, owning the gas and water works, would have the power necessary for the service, and would be at little additional expense for that necessary agent. The outlay for conductors, lamps, dynamos and other machinery would be the greatest expense. Its first cost would in a measure be returned to the city by saving the amount charged by private companies in excess of the actual cost of production, and also by the increased facilities offered for public lighting. It has become an established fact that wherever the electric light has been introduced great assistance has been rendered the police in discharge of their duties, and crime and criminals disappear from its immediate neighborhood."

Attorneys John G. Johnson, Lewis C. Cassidy, John R. Read and Silas W. Pettit, on behalf of the Western Union Telegraph Company, have filed a bill in equity, in the United States Circuit Court against Clinton P. Farrell, the receiver of the Bankers and Merchants' Telegraph Company, for this state, for the purpose of having enjoined the prosecution of the suit growing out of the troubles between the Bankers and Merchants' and the American Rapid Telegraph companies. The suit was begun some time ago by the receiver of the Bankers and Merchants', for the purpose of recovering damages for the cutting of wires and interference with the Bankers and Merchants' business. The sum involved in the suit is large, the amount named in the bill being $1,500,000. The Western Union obtained possession of the property of the American Rapid Telegraph Company in July, 1885, and has operated it since that time. It denies that it cut, mutilated or destroyed any of the wires, cables and appliances of the Bankers and Merchants' Telegraph Company, or of any other company, but, on the contrary, claims that only wires strung upon the poles and rights of way of the American Rapid Telegraph Company were arranged so far as necessary to attach them to the offices of the Western Union, so that they could be used.

The bill gives a history of the litigation growing out of the affairs of the Bankers and Merchants' and the American Rapid Telegraph Companies, and asks the court to decree to be void the alleged agreement between those companies of the 18th of October, 1883, for the maintenance of their wires. An accounting is also asked for between the American Rapid Telegraph Companies, especially the one doing business in Connecticut, and the Bankers and Merchants' Telegraph Company, to ascertain and determine which and how many of the wires strung in the State of Pennsylvania upon the poles and rights of way of the American Rapid Telegraph Company by the Bankers and Merchants' Company are or were at any time the property of the American Rapid Company, by reason of the cost of the same having been charged against the latter. It is also asked that the defendant be directed to make answer to the matters alleged in the complainants' bill.

A bill of complaint has been filed in the United States Circuit Court on behalf of the Edison Electric Light Company asking to have the Keystone Light and Power Company enjoined from the making of an alleged infringement upon eight patents held by the complainant. The court is asked to restrain the defendant company from proceeding with the construction of its incandescent electric light plants. The suit is of the same nature as the one pending in Trenton.

The new telephone company which has just been organized under the title of the New Jersey Southern Telephone Company has been promised great encouragement, and will start business with rates below those of the Bell companies. The company will erect its wires in the ten counties south of Trenton, and will employ the Emnor patent, by which sound messages are sent by a broken or intermittent current instead of by the Bell continuous circuit system.

Director Wagner has authorized the board of city trusts to open Front street from South to Vine for the underground conduits for electric light wires.

It is understood that an electric motor will shortly be put in operation through a line between Harrisburg and Steelton, a distance of two and a half to three miles.

PHILADELPHIA, May 17, 1887.

BOSTON.

Gas and Electric Light Interests.—Underground Wires.—Police Signal System Authorized for Boston.—New England Telephone Co.—The Bill to Regulate Telephone Charges.—The West End Railroad to try Electricity.—Personal Mention.

AT a recent town meeting in Brookline, Mr. W. W. Potter asked that the selectmen give good reasons why the town did not have better electric lights, and made a statement to the effect that in Boston light by electricity could be obtained at hardly more than one-half the cost of light in Brookline.

The selectmen report that the electric light now furnished to the town is not the same as that exhibited in 1885, but that, as far as practical results go, an equally good light is furnished. The light now used is the one arc, of a so-called 1,200 c. p., the light being furnished at a cost of 50 cents per light per night. The light used in Boston is 2,000 c. p., and is furnished at a cost of 65 cents per night. The selectmen acknowledge that they do not know the exact candle power of the light furnished to the town, and that, as far as they know, no satisfactory tests have been made by anybody. The reason given by the board for the high cost of the lights is that, as a contract is made for one year only, light cannot be furnished as cheaply as when the contract is for a longer time. They, as a board, do not think that, under the conditions imposed by them on the light company, the price of 50 cents per light for each night is exorbitant, and although an offer has been made to light the town with an equally good light, and at a cheaper rate, provided a large contract can be made, they do not feel at liberty to enter into a contract for more than one year. The above report will be submitted to the town, and the selectmen advise that the contract of last year be renewed, they being satisfied that the cost is reasonable and the light as good as can be obtained for the money.

At a meeting of the Newton common council, the committee on fuel and street lights recommended that contracts be made with the Newton Electric Light and Power Co. for the entire street lighting of the city with the arc, incandescent and oil lights, which would enable the committee to light the streets in a satisfactory manner within the appropriation. The committee investigated and witnessed an exhibition of the Edison municipal incandescent system of Portland, Me., where it appears to give general satisfaction. It is proposed to have 71 arc lights, to be lighted 20 nights in the month, from sunset to sunrise; also to have the electric light company furnish 700 incandescent lights, 400 to be of 25 c. p., and 300 of 20 c. p., to be burned 20 nights in each month, from sunset to midnight, at $15 per light per annum. An order was offered by councilman Redpath, authorizing the committee on fuel and street lights to contract with the electric light company to furnish 71 electric arc lights, to be lighted 20 nights in each month, and to burn from sunset to sunrise, the lights to be of 1,200 c. p. and to cost 50 cents per light per night. After a lengthy discussion the order was adopted.

The board of selectmen and the president of the Woburn Electric Light Co., have signed a contract to light the town for three years. By the terms of the agreement the company is to furnish 40 arc lights to be run until 12 o'clock, and seven to burn until daylight. By this plan all the gas lights will be displaced and a portion of the gasoline. These lights, by the terms of the vote of the town, will be furnished for $2,500 per annum. There can be no doubt that as much gas will be consumed in the future as in the past, as the town is rapidly increasing in its population.

The fight at the State House between the gas companies and the electric light companies is attracting considerable attention. It was practically initiated last year, when the gas companies of the state petitioned for authority to establish and maintain electric light plants. The gas companies were defeated but came up smiling this year with an armful of petitions. Twenty-three gas companies, through their legal representatives, petitioned the general court for authority to furnish electric light and power. At present there is no law to allow or prohibit gas companies maintaining electric light plants. The gas companies are simply under the supervision of the gas commission, while the electric light companies have no restrictions. Last year six gas companies obtained special charters granting the right to establish electric light plants. They are aware that there is no law to prohibit them from so doing now, but prefer to have some specific law giving them permission. Two bills have been rejected, and a third known, as the Hartwell bill, has been refused engrossing. This bill authorizes existing gas companies, with consent of the gas commissioners, to engage in the business of generating and furnishing electricity for light and power. The electric light

Digitized by Google

companies want the gas companies kept out from places now using electric lights.

In the Massachusetts Legislature, on the 5th inst., Mr. Savage of Taunton, when the House took up the bill to authorize gas companies to furnish electric light, opposed it as in the interest of a monopoly of artificial lighting. He said the gas companies will swallow the electric light companies, and that they do not ask for this bill in good faith. Gas making is more profitable than the manufacture of electric light, and if the bill passes, the gas companies will dictate whether or not the people shall have electric lights. Mr. Hallett, of Nantucket, believed that a general law as proposed was in the interest of gas consumers. Mr. Wadlin, of Reading, doubted whether the gas companies wanted in good faith to make electric light. Mr. Monk, of Braintree, moved to amend so as to make gas companies apply within two years of the passage of the bill for permission to manufacture electric light. Mr. Walker, of Worcester, supported the bill as in the interest of consumers. He believed that gas companies, with their plant, could furnish electric light cheaper than the present companies incorporated for that special purpose, and he predicted that it would not be long before the electric light would be sold for one-third of its present cost. The extraordinary power of the gas commissioners, he argued, would be ample to prevent any monopoly. The vote on ordering the bill to a third reading was 70 to 70. Speaker Noyes then voted in the affirmative. A roll call was ordered, resulting in 78 yeas to 76 nays. Mr. Upham, of Salem, gave notice of a reconsideration.

A petition was received by the Board of Aldermen, on the 1st inst., from the Edison Electric Illuminating Co., for leave to lay underground conductors connected with its stations for electric lighting purposes, in the district bounded by and including the following named streets: from the corner of Westchester Park and Beacon street, through West Chester Park to Chester square, through Chester square, Chester Park, Albany, Lehigh, South, Kneeland and Federal streets, Atlantic avenue, Commercial, Causeway, Nashua, Minot, Lowell, Brighton, Leverett, Charles, Pinckney and Brimmer streets, and through Beacon street to West Chester Park.

The New England Telephone Co., are completing their nine partition conduit through Tremont street, which was stopped by cold weather last fall.

The cities committee of the Legislature have reported a bill authorizing the board of police of the city of Boston, to introduce a police signal system in said city. The bill also authorizes the board to draw upon the city treasurer for money to introduce the system, the amount not to exceed $75,000, and the same to be paid out of the fees for liquor licenses. The privilege is given of attaching the wires for the system to any structures now wanted for wires.

At a meeting of the directors of the New England Telephone and Telegraph Co., on the 27th ult., a dividend of 75 cents per share was declared, payable Monday May 16, 1887, to stockholders of record at the close of business Wednesday, May 4, 1887. The transfer books will be closed from May 5, 1887, to May 15, 1887, both days included.

The following table shows the results of the New England Telephone and Telegraph Co.'s business for the quarter ended March 31, the first quarter of the fiscal year:

	1887.	1886.	Increase.
Gross receipts	$239,908	$220,744	$19,164
Gross expenses	165,461	156,837	8,624
Net earnings	$74,447	$63,907	$10,540
Constructions	3,550	899	2,651
Surplus	$70,897	$63,008	$7,889

The committee on mercantile affairs has reported a bill to fix telephone rates. Senators Alger, of Middlesex, and Cook, of Essex, and representatives Taft, of Palmer, and Boyden, of Foxboro, dissent. The bill reads:

Section 1. No individual, company or corporation, now or hereafter owning, controlling or operating telephone lines in this state, shall charge for the use of a telephone except as follows: In cities having at the last census a population of 100,000 and over, a sum not exceeding $6.50 per month shall be charged; if less than 100,000 and more than 50,000, not exceeding $4 per month, less than 50,000 and more than 10,000, $3.50; towns of less than 10,000, $3.

Sec. 2. Any person or corporation violating any provisions of this act shall be deemed guilty of a public offence, and on conviction shall be fined a sum not exceeding $25.

Sec. 3. This act shall take effect July 1, 1887.

The managers of the West End railroad, who control also the Cambridge railroad, have decided to run an electrical car between Harvard square and Boston. The power will be supplied by the Cambridge Electric Light Co. The car is being built in New York, and will be in use within a month.

J. N. Keller, Genl. Manager of the New England Telephone Co., has resigned. It is understood that he takes a position in the new company, for the introduction of superheated water for heating purposes, which Mr. Theo. N. Vail and others are promoting.

David B. Parker, supt. of the Boston division of the New England Telephone Co., has resigned, to take a position with the American Bell Telephone Co., as special agent; a position made vacant by the death of R. S. Boyd.

BOSTON, May 16th, 1887.

CHICAGO.

The Gas Trust and Electric Lighting.—The Tower System of Overhead Wires in Cities.—Strike at the Standard Electrical Works, Cincinnati.—Increase of Electric Lighting at Zanesville, O.—Western Business Notes.—Organization of the Chicago Electric Club.—Telephone Rate Regulation Before the Legislature.—A Proposed City Tax on Telephones in Chicago.

YOUR readers have doubtless noticed with interest the special press despatches recently sent out from this city, telling of a new monopoly, one to take hold of gas and electricity as the Standard Oil Co. took hold of petroleum, and to be hated and feared as the Standard Oil Co. is hated and feared The current report is that the newly formed Gas Trust Co. has obtained control of all the local electric lighting companies and now has a virtual monopoly of all the gas and electric lights in the city, while statements have been made from the inside, acknowledging that a combination has been formed, and claiming that it is entirely in the way of economy in producing and serving good and cheap light. The negotiations were conducted more or less secretly, but so much has been made public that the matter may be considered intelligently now, and, while it appears that monopoly is probably aimed at and a good start made towards it, yet the outlook is not so black as it has been painted. The facts are that there were several companies here selling gas, not of uniform quality and at different prices, and a Gas Trust Company, with a capital of $25,000,000, took possession of them all, assuming their combined liability of ten to twelve million dollars. Up to the present time, the trust has made no changes at all, so far as consumers are concerned, though its intentions are said to be something awful. When this step had been taken another was made, and with an accompaniment of newspaper warnings and gossip of the wildest description. An electric light company was organized and incorporated under the name of the Chicago Arc Light and Power Co, $1,000,000 cash capital, the Gas Trust men at the head of it. The first thing it did was to get control of the Chicago Sectional Underground Co., with its valuable franchise and its seven and a half miles of conduit, and then it began to gather in the electric light plants whose wires run in the conduits. Up to this date it has purchased three Thomson-Houston plants, embracing 404 lights, and the Wunder & Abbott plant, consisting of 284 Ball lights. A Western Electric outfit of about 260 lights should also be mentioned in this connection, as it belonged to the Lake Gas Co. and passed into the hands of the Gas Trust Co. at the time of the consolidation. Out in the cold, we find large central plants of the Western Electric, American, Sperry and Schuyler systems, together with a host of isolated plants, so that the statement so freely made, that all the electric light systems of the city have been purchased, is something of an exaggeration, or, it may be, very premature, for counting the lights rented from central stations, something over one-half of them are now in the hands of the Chicago Arc Light and Power Co., and that is all at present. The men in the deal are strong Chicago business men, and we venture the opinion that if they take hold of the business as it is expected they will, build large central plants and supply such lights as are required for street lighting and commercial purposes, the result will be good for the city. There appears to be little chance for an oppressive monopoly, as there are plenty of electric light outfits in the market and plenty of power here to run them, and, moreover, the conduits in the streets are open equally to all, the city franchises expressly forbidding unjust discrimination.

There are more ways than one of running lines in cities, and where it is impracticable to go underground the tendency is to go upwards. In New Orleans, in March, a city franchise was granted, giving the right for fifty years to erect in the streets a system of towers or supports for the purpose of carrying all wires and cables, whether for telephone, electric light, telegraph or other electrical purposes, under the supervision of the commissioner of public works, the lower wires to be not less than ten feet above the roofs of the buildings near which a tower is located. The system to be used is that invented by Colonel Flad, of St. Louis, and it is highly recommended by all electricians who have examined it. The following comment is from a late issue of the *Western Fireman*:

The overhead wire problem has always been a serious one in every large city. For years the wires have been tolerated as a necessary evil, and as time has gone on the poles have become more and more numerous and unsightly, and the network of wires has become more and more intricate, an eyesore to the general public a menace and a hindrance to firemen, and a superadded element in increasing the fire hazard. This evil is no longer a necessary one in cities whose physical possibilities and enterprise enable them to go ahead and bury their wires out of sight, discarding the poles, and removing the whole trouble at one thorough sweep. This has been done in Chicago to a great extent, and successful experiments in other cities show that it is possible there. In New Orleans, however, as well as other cities on the bayous and gulfs of the South this course is impossible, on account of the impracticability of digging for the conduits. Even were these successfully laid, there would still be constant trouble from floods and moisture. It therefore became necessary to devise some other plan to remove the wires from where they would be a constantly recurring obstacle in the way of the fire department. The New Orleans firemen have again and again been hindered and annoyed by the overhead wires which have prevented the raising of their ladders, and have thus kept them from the seat of the fiery enemy in many instances. The scheme which will soon be adopted in New Orleans, and probably also in other cities similarly situated, contemplates a series of high towers to be placed at intervals, provided with means of easy access, and high enough so that the wires

Digitized by Google

will be strung far above the tops of the highest buildings. The main towers are to be not less than 300 feet apart, and will be so slenderly fashioned as not to obstruct the view to any appreciable extent. The illustrated account of these appliances, as published in the *Item* of New Orleans, gives some of the details of the scheme as follows:

"Not only the main towers, which are not to be less at any point than 300 feet apart, but the centre supports, will carry stand-pipes, with hose and nozzle attachments, permitting copious streams of water to be poured down upon adjacent buildings in the most effective manner possible. In addition, a light but staunch staging, that folds up at the side of the tower, may be let down so as to enable firemen to enter the upper stories of adjacent buildings or upon their roofs when it is desirable to run a lead of hose over housetops to some central point in the block. Windlass, or block and tackle, can be provided to expedite the hoisting of hose to the higher galleries for such a purpose. * * * * * * * * * *

"The towers will contain separate sections for the use of the telegraph, telephone and electric light companies, each company's wires to be isolated, as well as thoroughly insulated, yet of easy and safe access at all times to workmen. * * * New Orleans has solved the problem of conveniently and safely conducting the enormously accumulating electric wires in cities. The cost as compared with such devices in the way of underground conduits as have so far been devised is small; the electrical and mechanical obstacles are reduced to a minimum; they are in no appreciable degree a street obstruction, while they ought at once to reduce insurance rates by reason of the facilities afforded in case of fire—to say nothing of that higher reason, which appeals to every heart, the additional safeguard to human life."

The labor agitation during the past year has probably troubled almost every other class of manufacturers more than the electrical. We have heard of imperious demands of walking delegates, but do not know of any case before this month where an electrical shop has been closed by a strike. We refer to that of the Standard Electrical Works of Cincinnati. Their men all went out on Monday, the 6th inst., and work has not yet been resumed. The trouble, as we understand it, is that the workmen demanded a full day's pay for half a day's work each Saturday, the officers of the company naturally refusing to accede, although placing themselves in an embarrassing position, through the disturbance of their large business. The Standard Electrical Works make a specialty of the Hess guest call and fire alarm system, and have turned to good account the services of their apparatus at the recent disastrous hotel fire in Buffalo.

We notice that the city council at Zanesville, Ohio, have ordered 98 new electric lights for their streets, in addition to their old contract for about 30. Zanesville's experience is like that of a number of other cities that we could name—first, gas-light, then gas with a few electric lights by way of experiment, followed by almost exclusive use of the latter light. The tide seems to be running strongly in this direction.

The Standard Underground Cable Co., of Pittsburg, have issued a new and attractive edition of their cable circular, illustrating and describing the different kinds of cable that they furnish. Mr. F. E. Degenhardt, manager of their western sales department, reports sales of 10,000 feet of 100 No. 22 conductor cable to the Missouri & Kansas Telephone Co., and 2500 feet of 150-wire cable, No. 20, to the Ohio Valley Telephone Co.

The Western Electric Co. have leased from the Western Union Telegraph Co. a special wire for direct communication, a part of each day, between the offices of the company at Chicago and New York. It is reported that this company will soon build a $20,000 addition to their large factory. They report among recent large orders, multiple switch-boards for Chicago, Buffalo, Providence and Allegheny City; electric light outfits for Zanesville, Roodhouse and Salina, and Patterson cable for the Chicago Telephone Co., 26,000 feet, and for the Central District & Printing Telegraph Co., 16,000 feet. The Chicago switch-board will go in the new building described in your columns last month, and will be one of the largest multiple boards in the world.

Holmes, Booth & Haydens and the Sprague Electric Railway & Motor Co. have opened offices at 185 Dearborn street, for the sale of their specialties. Mr. C. M. Barclay will represent the Sprague company, and Mr. J. L. Barclay, Holmes, Booth & Haydens. The Telemeter Company have given their western agency to the Electrical Supply Co., and the C. & C. Electric Motor Co, will sell through the Central Electric Co.

The John A. Roeblings' Sons Co., of Trenton, who draw a good deal of the line wire used in the United States, have an establishment in Chicago, and are represented by Mr. George C. Bailey. They expect to remove on or about the first of June to Nos. 171 and 173 Lake street. This property, consisting of a lot 40x180 feet, with the four story stone front building on the south side of Lake street, running back to a court, was purchased by them lately and will be occupied by them for business purposes.

The Chicago Electric Club has been organized and incorporated by the following gentlemen, all of whom are well-known in the electrical field, Chas. J. VanDepoele, B. E. Sunny, Joseph Uhrig, F. S. Terry, Chas. A. Brown, W. J. Buckley, Aaron K. Stiles, W. J. Armstrong, W. A. Kreidler, F. G. Beach, J. P. Barrett and Chas. D. Schain. The objects of the club, as stated in the incorporation papers, are the promotion of social intercourse, the diffusion of knowledge in electrical matters, and the erection of a club house.

There are bills in both houses for regulating telephone charges in this state, but the time before adjournment is short, and it is not likely that action will be taken. The most interesting thing in the way of special legislation is the effort in the city council to impose a license fee upon the Chicago Telephone Co., the amount to be $25.00 per telephone. Such an ordinance was introduced in the council and was referred to the committee on licenses, who have reported in favor of its adoption. The committee found that Chicago gets nothing from its telephone company, while St. Louis collects 2½% of the gross earnings, with $5.00 additional for each pole. Suppose the aldermen and the legislators at Springfield pass the proposed bills, that is to say, reduce the maximum charge to $36.00 and then tax it $25.00 for license, the Chicago company would have left $11.00 per annum per subscriber. This would be $11.00 better than nothing.

CHICAGO, May 19, 1887.

PATENT OFFICE EXAMINATIONS.

[69].—The American patent system, so-called, is a failure. I am well aware that this statement will strike the average patentee with startling effect somewhat similar to the effect of a flash of lightning in a clear sky. Nevertheless I believe it is absolutely true. Many years have I studied this matter - and have carefully read not only the American side, which I believe has only been printed in the United States—but I have also carefully studied and considered the arguments and statements of facts as they have appeared in the Common's Committee of the British Parliament for the years 1829, 1857, 1865, 1871, 1872, the report of the Patent Law Committee of the British Association, and of many British and European writers. These British and European authorities throw a flood of light indirectly on the question now under consideration. I mean by the American patent system—the system of granting patents to inventors only after a preliminary examination into the patentability of the invention by clerks (called "examiners") of the patent commission. These *ex parte* contests to obtain a patent (including interferences and all other patent office proceedings, of course), now not rarely mount up to so high a figure as to actually rival—and often surpass—the enormous and extravagant costs of infringement suits in the United States courts. And when the actual test comes of the validity of the patent in an infringement suit before a Federal court—all these costly patent office contests are of no value or authority whatever. The whole ground must be fought over, inch by inch, just as though there had never been any contest over the same issues in the patent office. Before 1836, in this country, patents were granted to inventors on their making a formally proper application for a patent, and paying the government fees—just as it is now and always has been, substantially, in all the rest of the world. Our so-called American patent system by patent office examination dates only from the law of 1836. I need not say that in these patent office contests—as also it is well known in the Federal courts—it is "*The last crown piece that wins*"—as the French emperor said about the contest with the allies. As a patent cannot be said to have any money value (except a chance to fight in a United States court) until it has been at least once judicially declared to be valid by a federal judge—it is a puzzle to know of what possible use to an honest and meritorious patentee—these interminable and costly patent office proceedings can be. When the money bags come in behind an inventor, real or pretended, then the contest in the patent office is only to ascertain who has the longest purse. The bribery, corruption, favoritism, and general rascality that has too often been practiced in the patent office during the last two decades are too well known to require any extended reference here. This preliminary examination in the patent office serves to perpetuate and strengthen the very general belief among inventors and patentees that a grant of a patent monopoly by the government of the United States, is a guaranty of some sort by the government to protect the inventor in the enjoyment of the monopoly of the claims of the patent. Else, they argue, why does the government take so much pains to carry on these hotly fought contests in the patent office? When the owner of the patent actually "gets it through his hair" that a patent is no guarantee whatever of anything by anybody except that it gives the patent owner a chance to carry on an infringement suit, at his own expense, in a court of the United States, with the chances finally against him in the Supreme Court of the United States—he has become possessed of the knowledge of a wonderfully valuable "chunk" of patent law.

To be brief, is it not worth while for the inventors of the

Digitized by Google

country to consider the matter of inducing Congress next winter, to abolish these patent office contests, and to go back, substantially, to the system of granting patents in this country before 1836—as it is now and always has been in the rest of the world? There would be no chance then for a worthy and meritorious inventor to lose his patent in the interest of a rich and unscrupulous rival.

JOHN MC CLARY PERKINS.

Boston, Mass., May 11, 1887.

ELECTRICAL NEWS AND NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

ANNUAL MEETING, MAY 17TH, 1887.

THE meeting was called to order in the rooms of the American Society of Civil Engineers, 127 East 23d street, New York, at 8.45 P. M., by the President of the Institute, Mr. Frank L. Pope.

The President—We have met this evening to hold the fourth annual business meeting of the Institute of Electrical Engineers, for the election of officers for the ensuing year and the transaction of any other business that may come before the meeting. The first thing on the order of business is the reading of the reports. The secretary, I think, has his report ready.

On motion of Capt. Michaelis, duly carried, a nominating committee was appointed to present names for the offices to be filled for the ensuing year.

The President appointed as such committee, Capt. O. E. Michaelis, Mr. G. M. Phelps, Jr., and Mr. J. Wetzler.

The Secretary, Mr. R. W. Pope, then read his annual report as follows:

SECRETARY'S REPORT.

As the Institute is about entering upon its fourth year, it appears to be an appropriate time to review its record, examine the field of its operations, and prepare for extending its usefulness in the future. The reasons for its existence are more apparent than they were three years ago. While all of us realized at that time, that electrical industries were in their infancy, the importance of scientific training was not appreciated as it should have been. It is now generally admitted that the best commercial results can be obtained in the electrical field by following out scientific theories, especially where they have been confirmed by practice. If we have learned all there is to be extracted from the study and practice of electricity, the Institute has no mission. If, however, we are progressive, and desire to obtain further knowledge of the art as we perform our various duties in this growing field, then we should not only continue the good work we have undertaken, but seek to extend the usefulness of the Institute by bringing to its support all who are in any manner interested in the various applications of electricity, and are desirous not only of profiting by the experience of others, but are willing to contribute their own ideas for the benefit of their fellow members.

The Institute having now apparently passed the critical period in its existence, and attained a recognized scientific standing at home and abroad, far in advance of all other strictly electrical associations in the country, membership in it is correspondingly appreciated. It is the only association, national in its character, which brings into the arena of discussion all branches of electrical research, and it may be added that in none of them are such subjects so thoroughly and intelligently treated, and so accurately recorded, and published for the information of absent members, as well as for future reference. To build up such an organization, to secure the active support of patient, zealous workers until it attains full recognition as a worthy public institution is a difficult undertaking, and that we have reached our third anniversary with bright prospects for the future is a very encouraging fact.

Two previous reports have directed your attention to the importance of holding more frequent meetings, in order to awaken and maintain interest in the welfare of the Institute, which it was feared might lose ground unless opportunities were offered for occasional gatherings during the year. Acting upon these suggestions, four meetings have been held since the 18th of May, 1886. The proceedings of these meetings were very fully reported in the electrical journals, and were also copied in foreign electrical periodicals. They have been beneficial to the Institute in various ways, and it is to be hoped that our members will contribute during the coming year a sufficient number of papers to enable us to hold at least eight similar meetings.

Nothing whatever has been accomplished toward securing permanent quarters, and this is, perhaps, the most serious obstacle which remains to be overcome. The continued courtesy of the American Society of Civil Engineers, in granting us the use of their rooms for our council and general meetings, while most heartily appreciated, does not satisfy the natural desire for a home of our own, and until this end is attained, it is hardly possible that the full benefits of organization can be realized. The present condition of our affairs is such, that I believe a much better showing may be made during the coming year, and I see no reason why we should not move forward with confidence toward attaining that most desirable achievement in the history of any similar society—a permanent record of scientific papers and discussions of which every member should be proud, based as it is, upon the intelligent researches of its supporters.

Respectfully submitted,

RALPH W. POPE,
Secretary.

New York, May 17th, 1887.

On motion the secretary's report was received and ordered printed in the transactions.

The President—The list of members shows a healthy and continuous growth. I think we may congratulate ourselves on the interest that is being taken by the electricians of the country in the prosperity of the society, which is evinced in the best possible manner by sending their names in as candidates for membership, and we may congratulate ourselves also on the quality of the new accessions as well as upon their number.

We are now ready, I believe, to proceed to the election of officers, and Capt. Michaelis will read the report of the nominating committee.

Capt. Michaelis—The committee appointed to make nominations have availed themselves of information received from members. There has been discussion of the subject of filling vacancies during the past month—ever since the last council meeting—and their prompt action is due to the fact that they were well informed in regard to the wishes of the members, and in suggesting names they have not probably strictly followed the idea which is the basis of our constitution with regard to geographical distribution, but they felt that during the early years of the society it would be well to have on the board of managers, men who could attend its meetings and be active in forwarding the interests of the Institute. In regard to one nomination, in which the feeling was unanimous, they are sorry to have to report that they could not meet the unanimous wishes of the members they have come in contact with during the past month, and that is in regard to the office of president. It has undoubtedly been the wish of every member of this society that our present distinguished president would be willing to accept another term; but he has positively declined notwithstanding all influences that were brought to bear upon him. He will not accept the office again, and his reasons are mainly based upon what he considers the best interests of the society. In the first place he desires to establish the precedent that there should be rotation in office, and that one term is sufficient; but I am glad to say that he has consented to permit his name to be used as a candidate for vice-president. The committee have therefore nominated for the office of president a gentleman than whom there is no other who has shown more interest in our progress, who has done more for us; we nominate for the office of President, Mr. T. C. Martin; for Vice-Presidents to fill the full term of two years, Mr. F. L. Pope, Col. R. R. Hazard, and Prof. W. A. Anthony; for Secretary—it is needless to state the committee's nominee—our present incumbent, whose able report we have just listened to with great pleasure, Mr. R. W. Pope; for Treasurer the committee has transferred one of the managers of the Institute—as the present treasurer has been promoted to be vice-president—we nominate (two of the committee do at least) to that office, Mr. George M. Phelps, Jr.; for Managers, Mr. Schuyler S. Wheeler, Joseph Wetzler, A. C. Fowler and William Lee Church.

No other nominations being made, the gentlemen named by the committee were in due form elected to the positions named respectively.

The vacancies arising from the resignation of Mr. T. D. Lockwood, as vice-president, and the transfer of Mr. G. M. Phelps, Jr. to the treasurership, were filled by the council who appointed Prof. Elihu Thomson, Vice-President, and Mr. E. P. Thompson, Manager.

The President—We are now ready for any other business.

Mr. Phelps—I have a resolution to offer. We have all heard in the able report of the secretary the remarks which he has made in respect to our want of a habitation, and the fact that we are still indebted to the kindness, but at the same time charity, of others for a roof over our heads when we get together. It is not disagreeable to come to the house of the Civil Engineers; it is always a pleasure, but at the same time we would all be happier and the society would be more useful if we had our own roof; the desire for that is very general, and some of us are of opinion that we are better able to accomplish something in that line than we have thought we were, if we would really put our hands to it and undertake it seriously; and with the view of having it done at once, I would offer a resolution in hope that it will bring out an expression of opinion and a favorable vote.

Resolved, that in view of the general interest evinced for three years past by members in proposals for some permanent quarters for the Institute, a committee be appointed at this meeting to report at the meeting to-morrow on the best plan to be adopted and the sum necessary for the purpose named.

The resolution was adopted.

Digitized by Google

The President—I will appoint on that committee Mr. Phelps, Mr. Martin and Mr. Hamilton.

On motion, duly carried, the following resolution was adopted:

Resolved, that the council be instructed and authorized to proceed to incorporate the Institute under the laws of the State of New York, appropriate to such society, and with power to designate from their own number a Board of Trustees.

Mr. Wheeler gave notice that at the next meeting he would offer the following amendment to the rules.

"The council shall have power to elect juniors who have been engaged in electrical or cognate interests for one year or more. These juniors shall not have the privilege of voting, but shall be entitled to be present at the meetings and take part in the discussions. They shall be required to pay one-half the initiation fee and five dollars annually, with one copy of the transactions, or three dollars annually without."

An informal discussion of the measure proposed by Mr. Wheeler, followed, eliciting a very general inclination to adopt some appropriate method of extending the advantages of the Institute to students and beginners in electrical work.

The President—I would say that the English Society of Telegraphic Engineers and Electricians, of which I have been a member almost from the beginning, has a class of membership of that kind designed for the same purpose that we are trying to accomplish. I do not recollect precisely what the regulations are, but of course that can be considered with other matters that will come up for discussion. That class was established after the society had been in operation some five or six years, and evidently was intended to supply a need which had manifested itself.

Capt. Michaelis—At the request of several members I desire to offer the following resolution:

Resolved, That the Institute desires to place upon record its appreciation of the services rendered by its retiring President, Mr. F. L. Pope, and its regret that he has deemed it for the best interests of the Institute to decline a unanimous tender of re-election.

The President—I thank you very much, gentlemen, for your kind appreciation of my services. They have by no means been what I would like to have made them. But circumstances have prevented my being in attendance at a great many of the meetings. I have always endeavored to be on hand when I could. I am sure that you will find that you haye not made an unprofitable exchange in the worthy successor that you have elected for me, and I feel sure that we shall all pull together, and make Mr. Martin's administration the most successful and prosperous one that the Institute has yet seen.

The meeting then adjourned.

GENERAL MEETING, MORNING SESSION, WEDNESDAY, MAY 18TH.

The meeting was called to order at 10.45 A. M., by the retiring President of the Institute, Mr. Frank L. Pope.

Mr. Pope delivered the following address:

Members of the Institute and Gentlemen:

In bidding you welcome to the Fourth Annual Meeting of the Institute of Electrical Engineers, it affords me much gratification to see such a large and representative attendance, and to note the evidently increasing interest manifested by the electricians of the country in the welfare and prosperity of our organization.

The year which has elapsed since our last annual meeting has proved one of unusual prosperity in all branches of legitimate business having to do with the manifold industrial applications of electricity. Without exception, so far as I am aware, the manufacturers of electrical machinery, apparatus and supplies are all fully employed; some of them are working overtime, and many of them have in contemplation or actually in progress extensive additions to their facilities.

While rapid development, enlargement and extension seems to be at present the rule in every department of the science and art which we as an organization especially represent, it may not be amiss to refer to the exceptional progress which has been made in certain specific directions since our last meeting. Among these may be mentioned the transmission and distribution of mechanical energy through the agency of electric motors, and especially the application of these to minor branches of manufacturing in large industrial centres, and to the propulsion of street railway cars; the largely extended employment of accumulators or storage batteries for the lighting of buildings and of railway passenger cars; and the introduction of long-distance incandescent electric lighting, which has at length, apparently, been made both practicable and profitable by the employment of alternate currents and induction apparatus. Last, but not least, should be mentioned the new art of welding metals by the aid of the electric current, which seems likely to occupy a vast and immediate field of usefulness, and to create numberless new industries, to say nothing of revolutionizing some of the existing ones which have come down to us almost unchanged from the days of Vulcan and of Tubal Cain.

I am sure that it will be a source of gratification to you all to learn that the prosperity of the Institute of Electrical Engineers has kept fairly abreast with that of its members and co-workers in their individual and professional capacities.

The series of monthly meetings, each preceded by a dinner, which have been held in this city during a portion of the past year, have proved to be most successful and enjoyable reunions, and have certainly done much to strengthen the Institute, by increasing the interest of non-resident members as well as of those residing in the more immediate vicinity of New York.

Several exceedingly interesting discussions which have taken place at these meetings have been reported in the professional journals on both sides of the Atlantic, and thus the information brought out has been made available to the profession generally. It is proposed to continue this commendable innovation during the coming year, and I have no doubt but that it will henceforth become a permanent feature of our proceedings.

The courtesy and liberality of our much esteemed sister society, the American Society of Civil Engineers, has enabled us to enjoy for another year the hospitality of the convenient and comfortable rooms in which we are now assembled.

While I feel sure that every member of the Institute appreciates to the fullest extent, the value of the assistance which has thus been rendered to us as a society in the days of our youth and feebleness, yet in the judgment of some of our most esteemed members, the time has arrived when we may feel justified in making a determined effort to secure adequate, commodious and convenient headquarters of our own. Within a day or two past a movement has been set on foot to raise the necessary funds to carry out this project in a fitting manner, and I am more than gratified to say, with excellent prospects of success. The undertaking will be presented to-day in a definite form for the consideration of the members, and I feel certain that each and all of you will individually do everything in your power to insure its early and complete success. It is hardly necessary to say, that the establishment of the institute in a building of its own, equipped with a library, reading room, and perhaps, ultimately, with an experimental laboratory, will give us a standing second to that of no other institute in the world devoted to a special branch of art or science; it will directly benefit every industrial enterprise in the country, having to do with electricity; it will increase the confidence of capitalists in the importance, remunerativeness, and stability of electrical enterprises, and will in every possible way be of the utmost advantage not only to our own members, but to all who are in any way connected with electrical enterprises. I trust, therefore, that my successor in the honorable position of President of this Institute, may be enabled to signalize his administration by the completion of this most desirable undertaking.

In conclusion, I desire to tender my acknowledgments to the officers of the Institute and the members generally for their kind and hearty co-operation in carrying on the affairs of the organization during the past year. (Applause.)

Gentlemen of the Institute, it gives me great pleasure to introduce our President for the coming year, Mr. T. C. Martin, of the *Electrical World*, who is well known by reputation to you all.

Mr. Martin then took the chair as President of the Institute, and read the following address:

Fellow Members of the Institute:

Your action last night, placing me next in succession as president to so distinguished an electrician as Mr. Frank L. Pope, and so soon after Dr. Norvin Green had occupied this chair, is one that only the results can justify. Although my connection with the Institute dates back to its foundation, and although in the three years of its existence I have been afforded the opportunity of participating in its management, I cannot venture to regard your decision as entirely personal. I would interpret it rather as a generous recognition of the fact that the Institute has still the larger part of its initial work to do, and that that work must be carried out chiefly by the younger element, which constitutes an ever increasing part of the membership. For this great honor, and for this sign of your confidence, my thanks must, therefore, find their best expression in what the Institute achieves during the current year.

We stand to-day at an important stage in electrical investigation and development, and yet it is not given us to see or to say what will be its position in the long vista or perspective stretching through the second half of the present century. As Dr. Priestley reflected one hundred years ago: "It may be said that there is a *ne plus ultra* in everything, and therefore in electricity. It is true, but what reason is there to think we have arrived at it?" Priestley was of those who were permitted to gaze afar off at untrodden fields of discovery, but who did not enter in. To-day the evidence of what has been achieved tells us that the greater lies before. The time is one, in fact, when science, and such a department of it as ours, offers to the more adventurous and inquiring spirits the rewards that were once mainly to be found in geographical discovery and in the prosecution of trade, but which are wanting now when even the interior of Africa has been traversed, and when commerce is carried on at apparently a diminishing rate of profit to capital. The electrician has gained, meanwhile, a foothold on the Atlantic seaboard

Digitized by Google

of his new continent, and, subduing a wilderness of theory, speculation and doubt, has already gained some of the noblest provinces that ever rewarded the industry and the genius of man. But beyond him lie the ranges of distant mountains, and westward of their peaks is the territory out of which he has yet to carve a score of states unnamed. Toward that great west of his science the electrician advances, and even now he has the first fruits of exploration. But while there is this onward movement for the pre-emption and occupancy of virgin soil, we see going on an equal development in the realms already won, invention being heaped on invention, and improvement added to improvement. Speaking as one who had witnessed this change, Dr. Werner Siemens said recently: "We still remember the time when we listened with incredulous wonder to the strange fairy tale that the mysterious new force, electricity, could transmit messages with lightning speed across whole continents and the oceans which divide them; and that this same agent could precipitate metals in a solid form from their solutions, and change night into day;" and yet, as he went on to point out, this is not less the time "when the world-encompassing telegraph no longer suffices for the needs of intercourse, but must give place to the transmission of oral messages by the telephone over distances, in comparison with which the natural range of the human voice appears as nothing; when the latest fruit of the union of science and technology—electro-mechanics—in its rapid development, offers to mankind ever new and immeasurable fields for the investigation and utilization of the natural forces."

We are dealing, however, with the immediate present and have to keep pace with such a rapidity of achievement that our plans each day have to be adjusted to larger conceptions and wider horizons. The position was admirably described this month in a leading magazine by Mr. G. B. Prescott, Jr. "The improvements of methods," he said, "the refinement of machines and appliances, and the bringing of science down to daily work and business, moves on so swiftly that the new machine, or the new one of a year ago, is already old. The reduction of refractory ores in electric furnaces, where immense carbons, fed by the largest dynamos in the world, give a heat never used before, excited world-wide wonder only a few months since. Even the very recent railroad accident in Vermont has created a demand for storage batteries for lighting lamps in cars that is so active that every railroad shop in the land is examining new accumulators. Never in the history of any business was there such an eager desire to obtain new machines, new tools, and new methods as in the manufacture of electrical apparatus." This is well put. In fact, the electrical statistics of to-day are nothing short of colossal. To go no further than our own country, we find an investment and capitalization in simply the leading electrical industries—telegraphy, telephony, electric lighting, and electric power—of a sum of, at least, $350,000,000. There are in America about 700,000 miles of telegraph wire. Last year 820,000,000 telephonic conversations were held. Over 150,000 arc lamps, and incandescents, verging on 1,000,000, now instruct the public eye that the electric is the light before which all others must pale their ineffectual fires. At least 10,000 electric motors are employed in the most varied industries, and while the electric railways here are carrying passengers at the rate of more than 3½ millions annually, the extraordinary increase now going on in that branch promises that the figures will be doubled within the year, with at least from 50 to 75 electric roads in operation. When to these figures we add the thousands of dynamos and vats used in electro-plating, the countless electric appliances used in medicine, surgery, and the miscellaneous arts, and the endless variety of electric apparatus for convenience, safety, protection and comfort in the house, office, train or hotel, we arrive at sum totals dealing with which a statistician needs all his ability to mass and classify. It is no exaggeration to say, moreover, that in the electric industries, hundreds of thousands of our most intelligent citizens of both sexes find remunerative and agreeable occupation; nor is it an exaggeration to affirm that at a time when all great departments of manufacture must depend for success on the degree of technical culture and skill displayed in them, none rests on a more strictly scientific basis than ours.

Where in the midst of all this activity, where in a sphere of so much outgrowth, onlook and uplift, do we find the Institute? That is the question for us to answer. The Institute has in its three years of life done good unobtrusively, but it is not discharging its responsibilities nor carrying out its mission to the full. Our fellowship, though growing rapidly from among those already active in electrical pursuits, must be greatly enlarged to embrace the constant accessions to the electrical ranks. Cornell University alone has now 59 students in electrical engineering, and those young men as they enter on practice feel the need of association with the men already at work. Stevens Institute is sending out numbers of capable electricians, and but the other day I had the pleasure of meeting the zealous and enthusiastic "electricals" of the Massachusetts Institute of Technology. For all of them, and many others, we must provide a place in our membership.

But with an expansion of the Institute must come, as my predecessor, Mr. Pope, said last night, proper accommodation for the books, apparatus, portraits and documents of the Institute, fitting quarters for the secretary, and a place to preserve the numerous relics and mementos which are to be given us, but now lie dusty and neglected and widely scattered. The Institute must have a local habitation as well as a name. It should also, as suggested in a resolution adopted by you, be incorporated at as early a date as possible.

Another matter of importance is the strengthening of the ties of friendship between the Institute and kindred societies at home and abroad. We have here no end to serve but the promotion of science and industry, and to that end we are endeavoring to devote our energies with singleness of aim and purity of purpose. I would be glad to see steps taken so that any member of electrical bodies abroad shall be entitled, while in America, to enjoy all the facilities and resources of the Institute. I would esteem it a great privilege to be in any way instrumental in more closely uniting the organizations here at home. I may particularly mention, in this respect, the New York Electrical Society, which, though local in work, is the oldest of the kind, and has made a most creditable record. The feeling toward us on the part of that society is heartily kind and fraternal, and I do not see why the two bodies cannot be brought together, and, perhaps, by compromise and mutual concession, benefited in a close union. The first approaches have, indeed, been taken in the membership enjoyed by a great many of us in both organizations.

I might touch on other topics, but can close by one remark including them all: We have our work as a national Institute to do. It lies ready to our hands. It may not be easy of accomplishment, but at least the effort can be made, and we have it in our power to render the Institute more influential, more representative, more helpful. (Applause.)

The President—We have one or two papers here from members not present, which are in the secretary's hands and which might be taken up immediately. We will, therefore, have the paper by Mr. E. P. Roberts, of Cheyenne, on "Practical Experience with Storage Batteries," an important topic, and one which deserves the most careful attention of the members. The secretary will now read the paper.

Mr. R. W. Pope, Secretary—Mr. Roberts omitted sending a title for his paper, so I took the liberty, as an old newspaper man, of putting on a title myself—"Storage Batteries in Practice."

Mr. Pope then read Mr. Roberts's paper. (See page 224.)

DISCUSSION.

The President—The paper is now open for discussion by the members and others present. Mr. Roberts's work has gone, it seems, through a considerable evolution, and has got to what we may term the elementary basis. This subject was brought somewhat prominently before the National Electric Light Association at its recent meeting in Philadelphia, and I think we have more than one member present who will have some very pertinent and valuable views to express with regard to that particular development. If I might venture to call upon any of the members, I think Mr. Mailloux is very much interested in this subject at the present time.

Mr. Mailloux—Mr. Chairman and gentlemen: It is true that I am much interested in electrical storage. At the same time it does not necessarily follow that I know much about it. I was very much interested in the paper prepared by Mr. Roberts, and I quite agree with him that the most promising method of employing storage in lighting large areas will be by means of a series of groups of batteries suitably located with regard to the distribution of light over certain districts and supplied from a central station.

It is possible to so arrange matters that we can send energy from the central station to the various groups at a high potential, and thence distribute at a lower potential, saving copper in the conductors for carrying the energy and getting the benefit of distribution at a low potential. In nearly all instances it is found impossible to place the charging station in the centre, or equally distant from all the various groups. Usually it is found cheaper to buy land on the outskirts of a town and to establish a central station there. In the case of incandescent lighting, the idea of distribution by different sets of feeders has been adopted, and in some cases with a marked economy in the cost of conductors. I have in mind the case of a person interested in electric lighting who submitted to me some data regarding an installation in some city in Pennsylvania, where he obtained an economy of over twenty per cent in the case of omnibus wires or feeders for the mains, by adopting the plan of distributing the energy in fractions to those mains, so to speak, instead of using one set of feeders to distribute the energy to the main,—a set of feeders of large diameter—he found that he could save copper by using distinct sets of feeders of smaller diameter and striking the mains at points more favorably situated with respect to the particular groups of lamps. In this way, having divided the total number of lamps into groups on the map of the city, he was enabled to lay out his conductors, and that is exactly what it is proposed to do with the storage battery. I do not think that it is as yet the ideal system. It is far too young and full of deficiencies to compare with the systems that have been in use for four or five years,

Digitized by Google

with very able men studying their deficiencies and seeking to remedy them. But from what I know of the case I think that I can quite heartily sympathize with Mr. Roberts in his tribulations —I have no doubt he had quite enough of them; but I think if he had seen some of the more improved forms of battery that are now in the market, perhaps his labors would have been materially lessened.

The President—This point of the utilization of storage batteries in central stations was alluded to with some degree of prominence by my colleague Mr. Wetzler at Philadelphia, and I think that some of the figures that he then presented would be extremely pertinent on the present occasion. There also comes in the use of storage batteries in connection with the telegraph, which I think is very important and material. We have the precedent in England, and Mr. Hamilton has given that subject, I believe, some consideration here.

Mr. Wetzler—On the occasion that the president refers to, I brought out the fact that a company had been started at Haverford, Pennsylvania, to run an electric light station and to have an auxiliary storage plant, The idea was this: It is conceded that the maximum number of hours for lighting probably does not exceed four or five for incandescent lighting. During the remaining time an incandescent station is practically running much below its capacity. Now the argument was that if they could put in a number of engines, dynamos and boilers which could be kept running practically twenty-four hours, there would be a great saving in cost of installation and operating expenses. The way in which that was to be accomplished was by the installation of storage batteries. They have a certain number of dynamos there which they keep running, I believe, some twenty hours during the day, and during the time the current is not used directly from the dynamos it is stored in the batteries and drawn upon as occasion may require. I believe there are some 600 or 1200 cells now in operation, and I understand too that the distribution to individual houses has also begun, that is, placing a battery in each house. What the success of that station is to date I do not know, but I shall make it a point to inquire at the earliest opportunity.

The President—I think we would all very much like to hear Mr. Hamilton on the point to which I alluded.

Mr. G. A. Hamilton—So far I have had no experience at all with storage batteries; but I might say that telegraph companies have considered the feasibility of using them, and while they have not arrived at a definite conclusion in regard to them, so far, it seems that the number of cells that will have to be provided will make the plant cost so much that it will be impracticable to use them. The matter is still under consideration, however, and after we have had a little experience with it I may be able to say something on the subject. If we could group the potentials along one after the other, as we do with dynamos, it would simplify matters; but that seems to be impossible, because some of the batteries would be drawn upon much more than others. On the other hand, if we group them up—taking different groups on lines of different resistances—then we would need so large a number of cells that the first cost and the wear and tear of them after a while, would make the whole cost too much for us. So far, the storage battery does not compare at all favorably with the dynamo, for our use. Possibly within the coming year we may be able to say something more definite in regard to it, for it is possible we shall use it to some extent. I do not know what the experience has been in England, but I think they have only used it to a limited extent.

Mr. R. W. Pope—In conversation with Mr. Hamilton I understood that one of the reasons why dynamos were not more generally adopted for furnishing current at the large telegraph centres was because there were very few places where the demand for the current was sufficient to warrant the running of a plant for twenty-four hours continuously, nor when this was done could sufficient economy be gained to make it worth while to change from the primary batteries, ordinarily in use, to dynamos. I would like to inquire from Mr. Hamilton, in connection with this, whether it would not be possible, with the use of storage batteries, to utilize the dynamos in centres where it is not possible now to run them for twenty-four hours continuously? In Pittsburg, for instance, you are talking about putting a dynamo plant there.

Mr. Hamilton—Yes; within the coming three months the plant will be put in there. Wherever we have above 9,000 or 10,000 cells I think it would be advisable to put in a dynamo plant. But I doubt very much whether we could do anything with a storage battery, because we must have four or five different potentials at least, and you have to duplicate them; that would be ten different batteries at once, and then you have got to have a spare afterwards, and at $17, $18 or $20 a cell it is rather expensive.

Mr. Frank L. Pope—There is another application of the storage battery which has not been discussed at this meeting, respecting which I would like to say a few words which may be of interest. A short time since I was applied to by the president of a street railway company, in one of our largest cities, who is about to build a line over new territory about five miles in length, on which it is proposed to run something like twenty cars. He desired to consult me as to the practicability of working the line by electricity, and stated at the same time that there were insuperable objections to the use of an overhead conductor, and that very serious opposition would be made to the use of a conduit, or anything which would occasion the slightest disarrangement of the pavement. He therefore wished me to investigate the problem of running cars by accumulators or storage batteries. In the course of this investigation I examined a car which was being experimentally run on the Eighth Avenue line, in this city, by the Julien Electric Company, and I was very much more favorably impressed with the results attained than I expected, although it was easy to see that better work could be done with accumulators than was being done there. In the first place, like most street railway lines in New York city, the Eighth Avenue line is of the most miserable construction; a construction that would hardly be tolerated on a contractor's dirt road out in the country, and yet these street railway managers, who are using the most costly kind of motive power in the world—horse-power—are misapplying from half to two-thirds of it in battering their tracks and cars to pieces against each other. There is a fine opportunity in this field, it strikes me, for missionary work on the part of our sister society, the Civil Engineers.

To return to my subject, I undertook a careful investigation; I procured some cells and had them put under test by a careful and accomplished young electrician, a member of our society, and from the results attained by him I became quite convinced that it was possible to operate street cars at a cost something less than by horse-power, at all events, and possibly considerably less. It is difficult to get at approximate results theoretically, because no one seems to know exactly what average power is required to propel a street car. The load varies greatly at different hours of the day, and the resistance to traction also varies greatly according to the condition and amount of dirt on the track, whether wet or dry, and all that, and nothing but a series of practical experiments can possibly give us exact results. Nevertheless we were sufficiently encouraged by the results we did get to go on and build a new car, embodying all the improvements we could think of, such as excellent running gear, highly efficient motors, etc., and that car, I hope, will be ready for use within the next month or two. We intend to put this car into actual service among the horse-cars, on an existing line; to carry passengers with it, the same as the rest; and meanwhile to carefully observe the electric energy used, and the power required, and generally to get all the information we can, which, I presume, will be made available for public use when we are through.

I may add that our theoretical investigations have led us to believe that with a number of cells that can easily be put under the seats of an ordinary 16-foot street car, we can run the car something like 50 miles with one charge of the accumulators, which would enable us to do a full day's work of 16 to 18 hours by changing the accumulators once. This, I hope, we shall succeed in doing, and it will afford me much pleasure to report the results of the experiment at some future meeting.

Mr. Mailloux—I would like to make a word of comment on the remarks made by our esteemed ex-president, and it is this: I would submit that he could not run 50 miles with all the kinds of batteries that are now offered for sale, and I think it would be better for the president to say that with some batteries he could run 50 miles.

The President—I presume it is understood we are speaking of the most advanced appliances.

Mr. Frank L. Pope—I assume that one reason why we were employed to investigate the matter was to make sure that the railway company should not get a battery that would run only 25 miles.

Mr. E. P. Thomson—The success of a scheme often depends not only upon the device itself, but upon the man who has the device in charge. Perhaps no man is better acquainted with Mr. Roberts than I am, having roomed with him about three years at the Stevens' Institute, and worked with him in the laboratory one year. After graduating from the Institute he took the position of an ordinary mechanic, for the purpose of thoroughly learning the mechanic's trade, in the tool room in Singer's factory. I happened to work there also, at one time, and the men engaged there told me that they paid a hundred dollars to learn the mechanic's trade, so as to be employed by the Singer factory, whereas Mr. Roberts not only learned the trade, but was paid by the week. Further, he went to a factory for the manufacture of hats in New York, where he was foreman and general manager, and worked very hard and got considerable experience, fitting himself in that way for the practical application of the knowledge of mechanics. He was appointed as electrical mathematician by the United States Electric Light Company, and their success, probably, is greatly due to his designs of dynamos, and other machinery and lamps. At the Swan laboratory he was well known as a man who worked from eight o'clock in the morning to twelve at night. I have letters from Cheyenne, where he has been working right along for a long time, for eighteen hours a day. Having all this experience, and knowing

Digitized by Google

also that Cheyenne is the place where the electric light has been attempted to be run by a storage battery, and knowing that Mr. Roberts has had such experience, we are justified in saying that in this case the failure was not due to the man. Mr. Roberts is also an inventor, and he has probably been able to make up for defects in any details of construction, and so get the best possible results from the batteries in his charge.

The President—I was very glad to hear Mr. Thompson speak so highly of Mr. Roberts, and I think that Mr. Roberts deserves our hearty sympathy and consideration for his frankness in speaking on these topics, and for the readiness with which, from so distant a point, as Cheyenne, he sends us papers and brings his work to our notice and looks to us for encouragement and information with which to develop his work in the future.

Mr. Thomson—I would add that Mr. Roberts was regarded by the Brush-Swan company as the best man they knew of in the United States to take charge of the works at Cheyenne. He was paid a reasonable salary, and I know personally that they looked around for a great many men and tried several men before they succeeded in obtaining just the man they wanted in Mr. Roberts.

The President—The next paper on the programme will be one by Prof. Anthony, of Cornell University, "On the Differing Temperature Co-efficients of the Different Coils of a Fine Rheostat." (For Prof. Anthony's paper see page 220.)

DISCUSSION.

Mr. Wallace—What is the size of the wire?

Prof. Anthony—We never have measured the wire; it is all covered with paraffine.

Mr. Frank L. Pope—I would like to ask if Prof. Anthony knows of any experiments of that kind that have ever been made with American made wire, and whether the same discrepancy is observable there.

Prof. Anthony—I don't know of any such experiments. It is our purpose to make an investigation of this sort; but this is all I have to report in regard to the matter at present.

The Secretary—I think Mr. Prescott is here. We should be glad to hear from him.

Mr. Geo. B. Prescott, Jr.—Prof. Anthony states that the wire in this rheostat was of different sizes. Now, if the current passing through the rheostat was of the same strength in all the different coils, the tendency would be to heat the thin coils more than the thick coils, and I suppose that would need to be eliminated.

Prof. Anthony—In regard to that the current was not sufficient to heat the coils anyway, I suppose the current would not have heated the coils 1-100 of a degree.

Mr. Wheeler—The kind of current that can be used with a deflecting galvanometer is about 1,000 times removed from the current that would heat the wire.

The President—It struck me that Mr. Prescott asked a very pertinent question. Could Mr. Prescott give us any definite, positive information from his own work?

Mr. Prescott—Some two or three years ago Mr. Weston, with whom I am engaged, was making some fine measuring apparatus and he found very great difficulty in getting german-silver wire at different times that was of a uniform quality. For that purpose he made some experiments on his own account to determine just the nature of this variation and what caused it. What led to his immediately taking up the subject was a paper published a short time previously in England by Prof. Bottomley, who reported the discovery by some Cheshire man, of a new alloy which he called platinoid. He said this alloy was ordinary german silver with one or two per cent. of tungsten added. He showed by some tests that its specific resistance was very much higher and its temperature co-efficient very much smaller than german silver. I looked at his original paper and I could not find what the proportions of the german-silver alloy were. I had previously searched through all the works on the subject that I could find, and not one of them gave the proportions of this german-silver alloy that they used—not even Matthiesen. For instance, you will find in the ordinary tables in the text books, a statement of all the different alloys in which the proportions of each one are given, until you come to german silver, and there they say german silver, plain and simple. In this country I went to several of the makers of wire and asked for their proportions, and they seemed to use almost everything. After Mr. Weston had heard of this alloy of tungsten he thought he would investigate it. He made up some ordinary german silver and put some tungsten into it and kept on adding it until he got 10 per cent. and he found that it did not make any difference. But we found by varying the proportion of the nickel the resistance could be made almost anything, so that the resistance of the german silver is almost directly proportional to the amount of nickel. The effect of zinc was only that of a dilution; it had a mechanical advantage in making the alloy ductile, so that it could be easily handled. We also found that the temperature co-efficient varied inversely; so that the greater the amount of nickel you had the smaller would be the temperature co-efficient. We got results very much higher than had been obtained in England with this alloy called platinoid, which was undoubtedly a german-silver alloy with a high percentage of nickel. The temperature co-efficient we endeavored to determine, but we met with a difficulty, which was this: We had a bridge—the largest pattern made by Elliott, of very large wire and very few contacts. There is only one contact for a series of coils. It is called the dial pattern. We tried to get the temperature of the room very even and we got some very curious results. We found that the temperature co-efficient was in the reverse direction. It decreased apparently after a certain point. But as we never could be certain of the temperature co-efficient of our bridge we were compelled to abandon determining what the exact co-efficient of the wire was; but that question of the proportion of nickel increasing the resistance and decreasing the temperature co-efficient we proved beyond doubt.

Mr. Mailloux—I think it would be of interest to have Mr. Prescott state what is the largest specific resistance he attained with various proportions of nickel.

Mr. Prescott—In the Western Union Telegraph Co. they have a peculiar way of giving specific resistances. They use a very large unit, and it is termed the mile-ohm. It is the weight of a wire a mile long which will give just one ohm resistance. The ordinary german silver on the market has a specific resistance of 12,000 pounds to the mile-ohm; that is to say a wire a mile long having one ohm resistance requires 12,000 pounds of metal. We found by using an alloy of something higher than 30 per cent. of nickel that we got a mile-ohm of 38,000 pounds, something more than three times the specific resistance of the ordinary german silver on the market. The temperature co-efficient, as I said before, was so small that we could not determine whether there was none at all, or whether it was in the reverse direction with the apparatus that we had.

The President—This is an important topic and it would hardly be fair to dismiss it without having the views and opinions of the members more fully brought out. We have with us one or two gentlemen who have some very valuable information to contribute. Mr. Wallace could give us some very interesting data on the subject of this wire. It is, as Mr. Pope has already pointed out, somewhat significant that we are discussing an English apparatus.

We have with us also Mr. Carl Hering who has done, I believe, some very interesting work in this direction.

Mr. Wallace—Speaking of german silver, there are all sorts of mixtures on the market, and it does not surprise me at all that you do not get two samples alike. You can take the same mixture and pour it at different heats and get different results from exactly the same mixture. Then you may roll it too much or you may draw it too much, and if you do not anneal it enough you can pull it apart, and you will get all sorts of resistances in that way. German silver is a very uncertain metal to handle. I have made a great many tons of it and it is very difficult to get two batches alike.

Mr. Hering—I am sorry I cannot contribute to the general information on this subject. I have very little experience with german-silver wire other than in measuring instruments.

Mr. J. A. Powers—I can speak very feelingly on the subject of the quality of german-silver wire in the construction of the McDonald cut-outs, if you will allow me to be somewhat personal. I find that it is almost impossible for us to get wire that will wind twice alike. We wind it up in bands and with a certain definite number of layers. You are obliged to adhere rigidly to a certain routine in order to produce certain results, and all coils are wound up and measured at the same time, and we find that do the best we can, we will have more or less variations of the wire. We have been to a good many parties for our wire and have been very careful about the gauge, and more careful about the temper, but it still bothers us all the time to get wire perfectly uniform.

Mr. Mailloux—I can add an item of my own experience on the subject. Very recently I had occasion to use some resistance coils made for an electrical railroad signal system, and the manufacturer showed me two bobbins that he had wound. It was intended to use a resistance of 20 ohms of No. 18 wire. He showed me a bobbin which was wound with that resistance and another one on which he said he had to take a No. 20 wire and then could not get the required resistance, although the bobbin was full.

It would be very desirable to have researches prosecuted on the subject so as to have some definite understanding arrived at which would guide manufacturers in the making of german silver of standard specific resistance. Will Mr. Prescott state for our information whether he advises the construction of rheostats, for measuring purposes, made of wire having such a high resistance, and also whether such wire can be had in the market?
